While I do not believe that what is termed the general-purpose cow can successfully compete with the exclusive dairy breeds, yet it must be admitted that there are many good cows to be found among the beef breeds, and on almost every farm, one can find one or more cows that are above the average in dairy work. It is from these cows that the future dairy should come on the average farm. Of course, where dairying is to be made a speciality, one should begin with some special dairy breed, either by purchase or breeding from dairy bulls, and grading up. But the average farmer, who keeps from two to half a dozen cows, from which to raise calves and make butter for home use, selling the surplus, does not want the dairy breeds, because they are only profitable where one makes dairying a speciality.

But rather let farmers find out which are their best cows, then breed them to a bull whose mother was one of these best cows, as well as the grandmother, if possible, and in a short time one can in this way get a herd of cows better than the average, without much sacrifice of the beef qualities. I have tested Short-horn cows as high as 5 1-10% butter fat, giving thirty pounds of milk a day. Such cows are profitable anywhere, but, unfortunately, they lack prepotency, and, as a rule, no assurance that heifers from such cows will be better than the average, unless thay are bred to a bull from a superior cow. But where one persists in this line, using good judgment, they will be reasonably sure of success.

But there is another point one must bear in mind, and to this I attach great importance, and that is the feeding and care of the calves. It is the easiest thing in the world to ruin a cow before she is six months old, by improper feeding, and there is a world of difference in feeding a calf with an eye to beef, and one intended for dairy work.

If one is feeding for beef the food must be of such a character that it will form muscle and fat. If for the dairy we want to build nervous force, which is directly the opposite. The nervous cow is never the fat cow or the cow that lays on fat readily. I am quite sure that many good cows have been ruined while yet calves, by wrong feeding and care. The cow is largely a creature of habit, and the habit of laying on fat should never be encouraged in a calf intended for dairy work. There is nothing on the farm that I watch more closely than the growing calves, as on the care the first 18 months of their lives largely depends their future usefulness. I want them where I can see them every day and see that their habits conform with the work for which they are intended.

While we have only, and breed only, the dairy cow, yet were we in the position of most farmers we would follow the above suggestions. No ironclad rule can be laid down, but determination to better one's condition can always be accomplished, and there is plenty of room for improvement along this line on thousands of farms. A cow that will give a profit over her keep might just as well be kept as one that runs her owner in debt. I see many opportunities in the home dairy, opportunities which if taken advantage of, would drive hard times from thousands of farms.—W. E. KING in *Boston Cultivator.*

MANY dairymen have the impression that the per cent of fat in a cow's milk is constant from day to day, or at least that there are no sudden changes.

On the contrary, experiments show that the percentage of fat in the milk of single cows will vary from one half to one and a half per cent. Herd milk will also show wide variations but not to the same extent.

If the above facts were widely known there would be less surprise exhibited and less cause for complaint at the changes shown in milk, by the Babcock test.

IS THIS YOUR STORY?

"Every morning I have a bad taste in my mouth; my tongue is coated; my head aches and I often feel dizzy. I have no appetite for breakfast and what food I eat distresses me. I have a heavy feeling in my stomach. I am getting so weak that sometimes I tremble and my nerves are all unstrung. I am getting pale and thin. I am as tired in the morning as at night."

What does your doctor say?

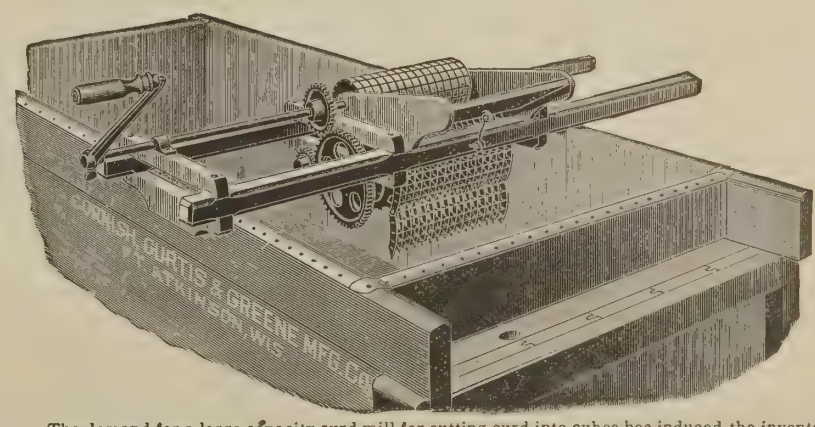
"You are suffering from impure blood."

What is his remedy?

Ayer's Sarsaparilla

You must not have constipated bowels if you expect the Sarsaparilla to do its best work. But Ayer's Pills cure constipation.

We have a book on Paleness and Weakness which you may have for the asking.



Write to our Doctors.

Perhaps you would like to consult eminent physicians about your condition. Write us freely all the particulars in your case. You will receive a prompt reply.

Address, DR. J. C. AYER, Lowell, Mass.

PIGS Eligible to REGISTRY, and First Class Stock, at Reduced Prices. Chester White, Berkshire, Poland-China and J. Reds. Thuroughbred and Grade Guernseys. Also Poultry. W. B. HARVEY, West Grove, Pa

Kasper Rotary Curd Mill.

The demand for a large capacity curd mill for cutting curd into cubes has induced the inventor to bring out the Kasper Mill. In construction the mill consists of a rotary cylinder made of knives in the form of cubes. Against these knives a wooden roll revolves with indentations to fit the knives of the cylinder; the curd being fed into the hopper is forced through the openings in the cylinder by the wooden roll. The cylinder is made in three sections hung on hinges, and, as it revolves, each section as it comes to the lower part of the cylinder, opens and allows the curd to drop into the vat, the section closing again as the cylinder revolves.

It is estimated that the curd from 7,000 lbs. of milk can be cut in from 7 to 10 minutes. The mill operates easily, being light running and adjustable to either hand or belt power. Simplicity of construction, durability and ease of cleaning are some of its principal features. All parts being galvanized or tinned prevents rusting. Weight of the machine complete is about 38 pounds. List price, $25.00.

CORNISH, CURTIS & GREENE MFG. CO., Fort Atkinson, Wis.

Inventors, Manufacturers and Dealers in Everything Pertaining to Butter and Cheese Making.

Agents for DE LAVAL ALPHA SEPARATORS.

FALLEN FROM ITS HIGH ESTATE.

Apropos of the remarks in another place, concerning the attitude of the *Country Gentleman* towards the National Dairy Union, we have a letter from Mr. John Haigh, proprietor of a creamery in northwestern Wisconsin, enclosing a page of the issue of May 4th, of which many so-called sample copies were distributed, and asking the not impertinent question: Does this paper belong to Armour & Co.

The answer must be a negative. Armour & Co. are not in the oleomargarine business any more.

PLAIN TALKS ON BACTERIA AS APPLIED TO FARM PROBLEMS.

[By Prof. H. L. Russell.]

Second Series, XVI.

BACTERIAL DISEASES OF PLANTS.

The one great phase of agricultural effort is the growth of plant life. The vegetable, rather than the animal, indicates in a way the highest development of the kingdom of life, for the plant is constructive, while the animal is destructive. Out of the mineral elements taken from the soil, and the carbonic acid and oxygen of the air, under the energizing influence of the sun's rays, the plant builds up vegetable tissue, and lays up for itself and for others, forms of life, a storehouse of nutriment. To foster and control this development is the great purpose of agriculture. Therefore, "he who can make two blades of grass grow where only one grew before", is a benefactor to the race as he increases the food-sustaining power of the soil just that much.

But the plant does not have an unhindered chance of development. In the economy of nature, other plant and animal forms prey on it, consuming its stored up food supply, destroying its constructive power, and in many cases killing the plant itself. While this is true under natural conditions in the field and forest, it is even more apparent in the cultivated crops that are raised by man. The cultivation of relatively large areas in a single crop, give conditions especially favorable for the dissemination of various pests. As a result, most of our cereal crops, but more especially fruits, vegetables and the like, suffer severely from the ravages of enemies, animal or vegetable.

DISEASES OF CROPS AND VEGETABLES.

For nearly every crop that the farmer can raise there is a host of bugs, flies, worms or other creeping things that are sure to attack his fields and gardens. More numerous than these and harder to combat is the host of vegetable parasites that prey on the succulent tissues of cereal or fruit. The phenomena of parasitism is very wide spread throughout nature, and among vegetable forms are to be found myriads that have forsaken the ways of honest folk, have turned their back on legitimate methods of plant growth, and are trying to work their way through the world by living at somebody else's expense. As a result, innumerable plant diseases exist, caused in the main by fungi, organisms of a vegetable nature that have gradually adapted themselves to a partial or complete condition of parasitism. While by far the great majority of these plant diseases are caused by fungi, still a considerable number and a constantly increasing list, are induced by bacterial parasites.

BACTERIA AS PARASITES OF PLANTS.

So much attention has been paid in recent years, to the relation that bacteria hold to animal and human diseases, that the fact has been overlooked until recently, that the same class of organisms possess the property of attacking and destroying vegetable tissue as well as that of animal origin. There are reasons why this particular class of germ life is not found in plants as often as in animals. For one thing, it is harder for them to establish themselves, and again, supposing that they do gain access to the succulent inner tissues, they find a medium that is less suited to their growth than that which is furnished by the animal body.

The plant has no mouth through which germs may enter into the susceptible inner tissues as is the case in the animal. Even the skin of the animal offers less resistance than the cuticle, bark, or outer membranes of many plants. It is true that the plant has innumerable breathing pores, but these do not connect directly with the protoplasm of the cell; then again, only gases, as a rule, can find their way through these minute openings.

But after all, the relative freedom of plants from bacterial enemies rests probably on the fact that the fare that they get in the plant is not wholly to their liking as a class.

If we recall a general law in bacteriology concerning the influence of reaction on development, it will help to explain this relation. As a rule, bacteria prefer an alkaline medium for their growth; fungi, on the contrary, thrive best in acid media. Now the juices of the plant are invariably acid and therefore are unsuited to the development of most bacteria. But, like all rules, this has its exceptions, and one finds that there are a goodly number of bacteria that grow quite as well in acid as in alkaline media Among these acid-loving forms are to be found a number of those species that are present in plants.

Again, the bacteria are prone to a nitrogeneous diet. They are meat lovers, and therefore, by nature, they cannot be regarded as vegetarians.

The general laws that govern the study of bacterial plant disease are practically the same as those that have been formulated for animal investigation. The study of this class however has been far less perfect than that of animal diseases, mainly for the reason that students of bacteriology, that are thoroughly familiar with the methods of work in this science, have not until recent years given any particular attention to the study of this group. For a long time, the text books on bacteriology, claimed there were no bacterial plant diseases, that it was impossible for organisms of this type to thrive in vegetable tissue. It is to an American investigator that the honor belongs of having first proved that a specific bacterial organism was the cause of a plant disease. Prof. T. J. Burrill, of the University of Illinois, in 1882, announced that he had found the cause of fire or pear blight to be due to a germ of this type. For a number of years his discoveries were discredited by European workers, but his experiments were so conclusive and were so completely confirmed by others that final acceptance could no longer be denied them. Since that time, the question of bacterial plant diseases has been closely investigated, both in this country and in Europe, and a very considerable number of these maladies determined. Some of these are of very great economic importance, as they are the cause of heavy losses in different parts of the country. Many of them have been more or less imperfectly recognized for years, often being attributed to some other kind of cause. The importance of a correct recognition of the true cause of any malady is self evident, as the habits and the methods of dispersal of different kinds of parasites vary so much that the means employed to control any one organism may not have any effect on another. Before a rational cure is found for any disease, it is generally necessary to determine with accuracy the cause of the malady and the conditions that may modify its appearance. Sometimes a remedy may be found by accident, as is said to have been the case with the Bordeaux mixture, but such instances are rare.

CARE AND TREATMENT.

There is not the opportunity, as a rule, to cure a bacterial plant disease, that may exist with a disease caused by a fungus, for the reason that the bacterial trouble is usually entirely within the tissues of the plant, and hence beyond the reach of external agents. Many of the fungus maladies are caused by parasites that settle on the surfaces of plants, and from this location work their way into the inner tissues. With such diseases, disinfectants applied externally at the proper time, are often very effective. While not much can be done in the way of saving a crop after it becomes affected with a bacterial disease, yet along the lines of prevention, much aid can frequently be given. This, however, necessitates a full knowledge of the disease, and the way it is distributed. One advantage that accrues to plants as against animals, is the possibility of checking the disease by removal of affected organ. Thus, an affected limb or branch may be cut off, before the disease spreads to other portions of the tree. Such a surgical operation cannot be practiced with animal forms, except in dire emergencies.

Gluten Feed.

Dairymen farmers, who have given Gluten Feed a trial, tell us it is the best milk-producing feed they can buy. If you want to lessen the cost of milk production and increase your dairy profits, give Gluten Feed a trial.

Write for full particulars and ask your feed dealer to keep Gluten Feed in stock for you. Address Dairy Department,

The Glucose Sugar Refining Co.,

The Rookery, Chicago, Ills.

A Case of Compulsion.

A Gossipy Letter. Rations—Butter milk from Skim milk.

Ed. Hoard's Dairyman:—I want you just to be quiet now for a few minutes, and let me tell you what you have done for me, or I shall surely "bust". I would have told you long ago, but had no excuse for so doing, as every time I hunted up something that I wanted to ask, (any old thing to write about to get a start) some other fellow would have you telling all about that very thing, till now it seems as if there is nothing under the sun you have not answered twenty times. But still they seem never to get short of stock.

I found in Prof. Henry's book, however, one thing that I will be glad to have light on. In his rations from different states I see there are some fellows out beyond the Rocky mountains that are feeding 35 pounds of alfalfa hay, and ten pounds of grain besides. Now, what on earth do they mean? Do their cows weigh 2,000 pounds, or don't they know how to make a ration? The way I figure, 35 pounds of alfalfa hay contains protein 3.85, besides the 10 pounds of grain. Please, what kind of a cow needs so much protein?

But I started to tell you what good I have received from the Dairyman; last year was the first year I read your paper, and it kept me bothered all the time about feed; it sounded all right on paper, about that silage business, but when I began to study about building one, I would get scared and say, "O! it won't do down here," but I kept reading until I have decided firmly to build one, have already planted the corn to fill it, and I learned a great deal about preparing the land, from your paper. The land is so well prepared that today, five days after planting, it is coming up nicely.

I hope to be better prepared next winter, and if it rains through haying time this year I will at least have my silage and not have to feed old woody cotton seed hulls at as high as $5 a ton and have at least two cows always off their feed, as I did last winter.

I learned how to—well, I would be telling all I know about the dairy business to tell what I learned from your paper. I have learned enough to make butter that sells at a good price and then I can't supply the demand. I also learned how to make a ration and feed each cow according to her ability to respond. But I taught myself how to make butter milk from skim milk. Mr. Editor, you seem to think it is all in churning it before it gets too thick, but I find it is all in cooling the milk as low as 85° F. (before separating as you have no foam in the way). I do not know what the scientists would say to this, but it may be (this does not apply to winter) that when the milk is left at 96° or higher, that the lactic acid bacteria do not thrive and some other kinds do and *vice versa*, anyhow, I can't make first-class butter milk, in the summer time, without first cooling the sweet milk.

Only one more thing now and I will stop, and it is about manure. I have seen my neighbors fix their barns so the liquid manure would all run off, to get it out of the way. Now, I try my best to keep mine, every drop of it.

And now, Mr. Editor, I hope you have read this—all of it. I have talked Hoard's Dairyman enough for you to have had a thousand new subscribers from here, but they don't believe in "book farming." Don't suppose I got more than twelve or fifteen, but will keep on trying

Tennessee. (?) R. T. Argol.

To avoid the alternative dire calamity, the editor held his peace long enough to read what is printed above, and tenders congratulations to the writer that the surplus pressure has been safely removed. He suggests, however, that in future there be less delay in opening the safety valve, to wit: the ink bottle.

While it is true that a good many questions have been adverted to more than once in recent years, it is also true that the same question seldom or never comes up for review or restatement in exactly the same form or without some change in environment, and there is, therefore, opportunity for putting it in a new light and thus bringing now one and again another detail into greater prominence. Moreover, no one can read the correspondence which comes to Hoard's Dairyman without learning something, and we are not without the hope that even the editors can discuss the various problems connected with dairying with more satisfaction to its readers than they did a year or more ago.

We suspect that in the case of the ration referred to, either the amount of alfalfa hay was over liberally estimated, or that a considerable proportion of it was not eaten Out in Utah they have such an abundance of alfalfa hay at times, that the farmer feeds it much as farmers in the middle west feed straw and corn stalks—quite as much to get it out of the way and mixed with the droppings, and thus increase the manure pile, as for its nutritive effect.

Calf Notes.

[Press Bulletin.]

Sterilized skimmilk is good for scours. The calves at the Agricultural College that receive sterilized milk are less subject to scours and recover more readily when attacked. The heating of the milk seems to produce chemical changes that help to prevent scours and at the same time enables the feeder to keep the milk in good sweet condition. Milk delivered at the creamery con-

tains large numbers of lactic acid germs. Unless these are destroyed by sterilizing, the skimmilk will sour in a few hours. When sterilized and cooled to the temperature of well water, skimmilk may be kept sweet from 36 to 48 hours. Feeding sweet milk at one meal and sour at another is very apt to cause scours and stunt the growth of the calf.

The stomach of a calf is delicate and sensitive and any change of feed should be made gradually. Do not change from whole milk to skimmilk faster than a pound a day, allowing from ten days to two weeks for the change. Before turning on pasture in the spring it is better to feed a little green feed and gradually increase the amount until the limit of the calf is reached. Otherwise the calf may suffer severely from scours by the sudden change to pasture.

Several complaints have reached us about skimmilk, intended for calves, souring, even when placed in tubs of cold water as soon as received from the creamery. Sterilized skimmilk will not sour until it is cooled to about blood temperature. A can of hot milk will warm a tub of water to about that temperature and as the milk is coolod at the same time the best of conditions are offered for the development of lactic acid germs. The tub of water only helps to keep the milk at blood temperature. Under such conditions the water is worse than nothing. If hot skimmilk is cooled in a tub it should be done by running water. A much better way would be to use a cooler and then place the can of milk in a tub of cold water in order to keep it cool.

Don't over feed. Calves are very greedy at feeding time and there is often a great temptation to give more milk than the calf can properly handle, thus causing them to scour. Overfeeding is undoubtedly the main reason why so many farmers are unable to raise good thrifty calves on skimmilk. At the college we find that calves from three to four months old will not stand more than 18 to 20 pounds daily per head, from seven to eight weeks old, 14 to 16 pounds and three to five weeks 10 to 12 pounds. (1 quart equals 2 pounds.)

Kafir corn meal is proving an excellent feed for young calves at the Agricultural College. It is constipating and aids materially in keeping calves from scouring. They commence to eat the meal when ten days to two weeks old. At first a little of the meal is placed in their mouths after drinking their milk, and in a short time they go to the feed boxes and eat with a relish. Our herd of thirteen calves, averaging eight weeks old, consume 2 pounds daily per head.

Never put corn, kafir corn meal or any other grain in the milk for calves. The starch of corn has to be changed to grape sugar before it is digestible. This change only takes place in the presence of an alkali and is done chiefly by the saliva of the mouth. When corn is gulped down with the milk the starch is not acted upon by the acids of the stomach but remains unchanged until it comes in contact with the alkaline secretions of the intestines. With hogs the stomach is small and the intestines long. This allows starchy matter to be digested in the intestines. The opposite is true with the calf, the stomach being large and the intestines short. Unless the starchy matter is largely digested by the siliva of the mouth, complete digestion will not take place in the intestines and the calf scours.

Flax seed meal or Blachford's meal, made into a jelly or gruel are good to mix with skimmilk to take the place of butter fat. Oil meal is frequently used for this purpose but, like skimmilk, it has a large amount of fat removed and is not as good as meal with the fat in.

Calves like fresh water. Any arrangement like the Dewey hog waterer that will keep clean, fresh water before them all the time, is the best way to supply it. Our calves drink between 7 and 8 pounds daily per head.

D. H. OTIS.
Kansas Experiment Station.

DAIRY MARKETS.

ELGIN, Ill., May 29—Butter—Offerings to day 215 tubs; bids opened at 17c and advanced to 18c, with no call sales; official market firm at 17½c: 109 tubs withdrawn. Butter last week, 17c, and one year ago, 16c.

CHICAGO, Ill,, May 29—Butter—Creamery, extra, 17½c; firsts, creameries, 16@16½c; seconds, 13½@14c; dairies, selections, 15c; extra ladles, 12½c.

Cheese—Full cream, Twins, new, good to choice, 8¾@9c; Young America, 9@9¼c; Swiss, 10½@13c; Limburger, 7@9½c; Bricks, new, 7½@8¾c.

Eggs—Fresh, at mark, cases returned, sold at 12c; cases included, 12¾c; duck eggs, 12@12½c; goose eggs, 12½c.

Bran—Market weak and 25@50c lower, with sales at $10.25@10.50.

Cattle—Trade was active at last week's best prices, or 5@10c higher than last Friday's lowest prices. Exporters were free buyers again, largely at 5 15@5.35. The top of the market was 5.60, with the bulk of the beef cattle at 4.95@5.35. Corn-fed westerns sold principally at 5.05@5.30. Straight Texas steers sold at 4.50@4.90. A big lot of 1,095-lb. western heifers sold at 5; distillery fed bulls, 1,240@1,261 lbs., 4.40, and feeding cattle, 4 25@5.15.

MILWAUKEE, Wis., May 29—Butter—Creamery fancy prints per lb. 17c, extras, 17c; firsts, 16@16½c; seconds 14@15c; imitations, 14@15c. Dairy—Selections, per lb. 13@14c; lines, 12@13c. Roll—Fair to choice fresh, 9½@10c; packing stock, 9½@10c. Market unchanged, with a fair local and outside trade of all kinds. Receipts 18,520 pounds.

Cheese—American full cream, new to choice fancy, 9@9½c. Brick—New choice, 7½c@7¾c Limburger—Fall, choice, 9@9½c; new choice, 7@7½c. Swiss—Drum choice, 12½@13c; block, choice, 10½@11c Market unchanged and moderately active, with receipts 5,480 pounds.

Eggs—Fresh per dozen, 12c, cases returned. Market unchanged; receipts 415 cases, which are readily salable.

PLYMOUTH, Wis., May 29—Cheese—Market to-day; 780 Twins, at 8c; 640 Young Americas, at 8¼c.

AVOCA, Wis., May 29—Cheese—On the Lone Rock and Muscoda Dairy board to-day, the offerings were 863 boxes Twins; market dull at 7¾c

FOND DU LAC, Wis., May 29—Cheese—Offerings 616 Twins and 150 Daisies; market steady at 8¼c.

SHEBOYGAN FALLS, Wis., May 24—There were 1,019 boxes of cheese sold on the call board here to-day, all the offerings being taken as follows: Seven hundred and fifty five Young Americas at 8¾c; 10 Daisies, at 8¾c; 90 Daisies, at 9c; 18 Longhorns, at 9c; 121 boxes Twins, at 8¾c; 25 at 8⅞c. Sixteen factories were represented on the board.

SHEBOYGAN, Wis., May 24—The sales reported to day were 360 Twins at 8½c, and 440 cases Young Americas at 9c.

MANITOWOC, Wis., May 24—Offers of cheese to-day were 150 boxes Daisies, 52 boxes Twins, 475 boxes Young Americas. All offerings Daisies and Twins sold at 8½c, Young Americas 8¾c

BRILLION, Wis , May 19.—The sales reported on the board to-day were 490 Twins and 668 Daisies at 8¾c, and 311 cases of Young Americas at 9¼c.

HORTONVILLE, Wis., May 18.—Offerings on board to-day were 722 Twins. Sales: 500 Twins at 8⅝c. Ruling price, Twins 8⅝c. Market moderate Next meeting June 1st.

NEW YORK, May 29—Butter—Creamery, western extras, 18½c; firsts, 17@18c; state extras, 18c; firsts, 17@17½c

Cheese—State, full cream, large white, choice, 8½@9c; small, 9@9½c.

Eggs—State, Pennsylvania and Western, 15@16c.

LITTLE FALLS, N. Y., May 22.—Butter—Sales 23 pkgs. dairy at 16@18c.

Cheese—Sales 40 boxes large colored at 8½c; 240 large colored and white at 8⅝c; and 3,848 boxes small colored and white at 9c.

UTICA, N. Y., May 22.—Sales 12 packages at 17c.

Cheese—45 boxes small white at 9⅜c; 440 boxes at 9⅜c; 120 small colored at 9⅜c; 40 boxes at 8¼c; 21 boxes large white at 8½c; 70 boxes at 9½c; 1,016 boxes large colored at 8½c; 923 boxes at 8⅝c; and 572 boxes on commission.

BALTIMORE, Md., May 29—Butter—Market firm; creamery separator extra, 19c; extra first, 17½c; creamery first, 17c; creamery imitation extra, 15@16c; lad'e extra, 13@14c; western store packed, 11@12c.

Eggs—Market firm; strictly fresh stock, 13½@14c.

PHILADELPHIA, Pa , May 29—Butter—Solid packed; separator creamery, extras, 18½c; firsts, 17½c; seconds, 17c; imitation creamery, extras, 16c: firsts, 15c; seconds, 13c. Ladle packed: Extra, 15c; firsts, 14c; seconds, 13c. Print butter: Creamery extras, 19c; firsts, 17@18c; seconds, 14@16c.

Eggs—Pennsylvania and nearby, 15c; western, 15c; southwestern, 14½c; southern, 13½@14c, loss off.

NEW ORLEANS, La., May 29—Market quiet, 18@18½c.

NEWARK, N. J., May 29—Market steady, 18½c for fancy creameries. Receipts liberal.

WASHINGTON, D. C , May 29—Market steady, extras, 18½c; choice firsts, 18c; fine imitations, 15c.

BOSTON, Mass., May 29—Butter—Market firm at 19c.

Cheese—Steady, 10c.

Eggs—Steady, 15c.

KANSAS CITY, Mo., May 29—Butter—Separator. 15c; Dairy, 13c.

Eggs—13c.

ST. LOUIS, Mo., May 29—Butter—Dull; creamery, 15@18c; Dairy, 12@15c.

Eggs—Steady, 11c.

CINCINNATI, O., May 29—Butter—Quiet, 18½@19c.

Eggs—Easy, 12c.

Cheese—Steady; good to prime Ohio flat 9½@10c

Latest quotations for fancy creamery; Buffalo, 17½c; St. Paul, 16½c; Minneapolis, 16@16½.

BALTIMORE MARKET.

BALTIMORE, Md., May 25.—Butter—The advance in price of extra separator creamery of two cents per pound, established last week at several of the primary markets in the west, communicated its evil influence to many other contributing sources, thereby compelling receivers at distributing centers to ask at least a portion of the increased cost, or waive all claim to compensation for handling contract makes of this variety. The unwisdom of permitting such counsel to prevail in a quarter wielding the influence claimed by Elgin, or any other one market, was never more manifest than just at this time, when a *faux pas*, such as that advance unquestionably was, would disturb all the conditions of trade at home and abroad as this advance did, and threaten the whole season's business in high grade creamery products. Buyers having been driven from separator creamery paid more attention to gathered cream and imitation creameries, thereby increasing somewhat the demand for these less favored varieties; near-by creameries also came in for a full share of the enforced increase in demand and profited therefrom, even to the extent of working off a proportion of the garlic-tainted products. Toward the close there was plenty of butter of every kind, at all prices, for any demand; and as there was a great pressure to sell, buyers had it their way. Storepacked has been in quite liberal supply so far this week; the demand continues good; we would advise that you ship no more rolls; pack solid. Creamery separator, extras 19c; firsts 18c; seconds 17c; gathered cream, extras 17c; firsts 16c; Ohio, extras 18c; firsts 17c; seconds 16c; Iowa & N. READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

Wanted—Man and wife on farm, to live with owner's family. Man for general work and care of cows. wife for general house work. Apply, A. JENNINGS, Brookwood Farm, Farmingdale. N. J.

For Sale—4 h. p. upright boiler and horizontal engine Bargain. R. J. MUDGETT, Jesup, Ia.

Wanted—Working foreman; must understand farming and dairying, feeding and care of stock how to run separator and engine. Also want to know where I can get Short-horn dairy cattle. ROBERT McFADDEN. Santa Ana, California.

For Sale—The choicest located 160 acre stock and dairy farm in Southern Minnesota. Joins town site of Windom, County Seat of Cottonwood County and only 25 miles from Iowa. House is 30x16 and 14x16 all two-story with addition and stone wall cellar 16x16. Barn is 40x45, 10-ft posts. Has also granary, corn crib, poultry house, good wells, etc., etc., and the Des Moines river flows through the pasture. 20 acres native timber on river, rest in field, pasture and tame grass. Creamery within one-half mile. Price only $35 00 per acre. This is a decided bargain. Act quickly. Call on or write for prices and terms to THOMAS E. SIME, Windom, Minn.

Creameryman, German, 32 years old, experienced in working up skim milk into small cheeses and who knows a market for same, desires a position in N. Y. or near by state. E. GURTT, 503 3d Ave., New York City.

Soja Beans—For soiling, ensilage and hay. Medium early variety. $2 00 per bushel; 5 bushels at $1.75 per bushel. Circular on growing for a 2 cent stamp. W. H. STODDARD, Carlinville, Ill.

Wanted—A good all round farm hand and dairyman. Must be a first-class milker. State references, ability and wages. BOX 120, Mt. Pleasant, Ohio.

We have sold our Schmidt's Treatment for Milk Fever to many prominent dairymen and cattle breeders. Mr. Chas. A. Sweet, of Buffalo, protects his most valuable Jersey herd with our remedy. GARDINER BROS., 220 E. Preston St., Baltimore, Md.

For Sale—Fifteen h. p. boiler and 15 h. p. upright high speed engine nearly new, also 6 h. p. engine. GEO. WOODRUFF, Adm'r, Janesville, Wis. 14-4

Scour Cure—Stops scours in calves. Large bottle $1.00. A. S. ALEXANDER, V. S., Evanston, Ill. 15-tf

Wanted—Farm superintendent on dairy farm in Waupaca County. Fine house and pleasant social surroundings. Permanent position on salary. Married man, with experience. Good references required. M. C. PHILLIPS, Oshkosh, Wis. 13-4

Tamworths, ready to wean, $10 each, or $15 delivered. Hermanville Farm, P. E. I., Canada. 32-52

Very Low Rates to Columbus, Ohio, via the North-Western Line. Excursion tickets will be sold at greatly reduced rates, from all stations, for trains arriving Chicago June 2, 3 or 5, limited to include June 13, account of meeting American Medical Association. Apply to agents Chicago & North-Western R'y 15-2

Excursion Tickets to Oshkosh, via the North-Western Line, will be sold at reduced rates, from stations in Wisconsin, June 5, 6 and 7, limited to June 10, inclusive, on account of I. O. O. F. Grand Lodge. Apply to agents Chicago & North-Western Railway.

Exceptionally Low Rates to Buffalo, N. Y., via the North-Western Line. Excursion tickets will be sold at greatly reduced rates from all stations, on account of Annual Meeting A. A. O. Nobles of Mystic Shrine, to be held June 14 and 15. For dates of sale and limits of tickets apply to agents Chicago & North-Western R'y. 16-2

Mr. Wheaton's Canadian Dairy Notes.

The Use of Hand Separators on the Farm. Data as to the Presence of Mold in Butter Packages.—Flavor of the Wood.—Transportation.—New Zealand Dairying.

ED. HOARD'S DAIRYMAN:—The feature of dairying that is coming rapidly to the front in this country, is the farm separator system. There is perhaps, more inquiry about farm separators than any other line of dairy machinery, at the present time. While a great many separators have been disposed of among farmers, the demand is nothing like what it will be within the next five years. Our dairymen are just beginning to wake up to the fact that the small separator for a herd of 10 or 12 cows will almost pay for itself in one year, in the increased amount of butter that can be made, as compared with the gravitation method.

What effect the general introduction of the farm separator will have on our co-operative dairy system is not easy to say at present. Where it is largely introduced into the special dairy sections, it may have the effect of curtailing the make of cheese at the factories. Upon the working of the co-operative creamery it should have a wholesome effect, especially where the cream gathering system is followed.

In Eastern Canada about all the creameries are run on the separator plan and the whole milk is delivered by the farmer, the same as to the cheese factory. In Manitoba and the northwest territories, the cream gathering plan is of necessity adopted, owing to the long distance that milk has to be drawn, and the farm separator would serve a useful purpose, in enabling the farmer to get all the cream out of the milk and to preserve it in good condition for butter making. We understand that many western dairymen are aiming at this plan if they have not already adopted it.

It may be difficult at the start to get all the patrons of a creamery to buy separators, but the advisability of doing so cannot be questioned, especially where the farmers live far apart, as is the case in the west. But why would it not be possible for the farmers to co-operate in buying these machines? By doing so they should be able to get them at a reduced rate.

One of the drawbacks is the high price charged for the small separators. When a farmer is asked $100 or so for a separator for the use of his dozen cows, he will think twice before signing an order for it. Though he would soon get back this expenditure in increased yield and a better quality of butter, it takes time to convince him of this.

While the representatives of the older separators, such as the DeLaval, Russian, Alexander, Mellotte, American, etc., are on the field and pushing matters for all they are worth, several new Canadian separators have recently appeared upon the scene and seem to be getting a good share of the business. Some of the new ones are the "National," "Canadian Ideal," "Waterloo," and from appearances they are likely to make some of the older ones get a hustle on.

Mr. L. C. Rogers, who has lately resigned the position of Instructor in butter making at the Ontario Agricultural College, to engage in the separator business, has recently published some data on the subject of farm separators, which are worth noting. From 150 trials made at the Ontario Agricultural College, in comparing the separator plan with the gravitation method during five years, in which a total of 7,600 pounds of milk was tested for each plan, the following table of results is compiled:

No. of tests.	Lbs. of milk skimmed.	Method of skimming.	Average of butter fat lost in skim milk.
150	7,600	Shallow pans	.38 p. c.
150	7,600	Deep setting	.31 p. c.
150	7,600	Separator	.10 p. c.

Investigations were also made to determine the loss of butter fat in skim milk at thirty-six farm dairies. Ninety-six samples were tested, which showed an average loss of .9 per cent of fat in the skim milk, which was equal to one-quarter of the total fat in the milk before being skimmed. If average normal milk contains 3.6 per cent of fat and 100 pounds of such milk make four pounds of butter, and if the butter is worth 15 cents per pound the butter fat would be worth 16.66 cents per pound. At this valuation, according to the above table, the value of the loss of butter fat from the separator plan would be 1.66 cents, deep setting 5.14 cents, shallow pans 6 3 cents and farm dairies 14.9 cents per 100 pounds of skim milk.

As to the actual value of the farm separator, Mr. Rogers points out that these machines will yield from one-half to one and one-half pounds of butter per cow each week more than if the cream were raised by the gravitation method and has compiled the following table showing what the gain from one to twelve cows will amount to in one year:

No. of Cows.	Gain of Butter per Week.	Value at 15 cents per lb. of Butter.	Gain of Butter for 40 Weeks or About 9 Months.	Value of Butter at 15 cts. per Pound.
	Lbs.	Cents.	Lbs.	
1	1	15	40	$ 6.00
2	2	30	80	12.00
3	3	45	120	18.00
4	4	60	160	24.00
5	5	75	200	30.00
6	6	90	240	36.00
7	7	1.05	280	42.00
8	8	1.20	320	48.00
9	9	1.35	360	54.00
10	10	1.50	400	60.00

This table proves pretty clearly that it will not take a farmer very long, with eight or ten cows, to pay for a separator. Not only does he get a larger yield, as compared with the deep-setting or shallow pan method, but everything else considered, gets a better quality of butter, whether it is made at home or at the creamery. So why should people hesitate about adopting improved methods when there is such conclusive evidence as to the advisability of doing so.

This branch of dairying is not written up just here with a view to "booming" the separator business for the manufacturers, but merely to show what we consider to be one of the coming features of dairying in this country and something that our dairymen will have to give special attention to in the near future, if they have not already done so.

At a recent meeting of the Butter and Cheese Section of the Montreal Board of Trade, Prof. Robertson gave some practical advice in regard to mold in butter packages. He recommended the dipping of the parchment papers, before being applied to the butter, in a solution made by mixing 1¼ ounces of formalin with one gallon of brine. This would prevent any mold from forming in the package, and as the formalin is not poisonous and tasteless, it would in no way injure the quality of the butter. Formalin was, however, in no sense a preservative.

[We are inclined to the belief that Prof. Robertson must have been misquoted in some way. Formalin is a very powerfnl preservative, and morever is of very decided poisonous properties. There is but little choice between using it in the parchment paper or in the butter itself. Such a suggestion is an open door to the use of preservatives in butter.—ED.]

A question raised by some of the cheese and butter exporters was that frequently in tubs or packages of butter, one to one and a half inches deep around the sides, the butter would have the flavor of the wood from which the package or tub was made. This was caused by making the boxes from green wood. The meeting strongly urged upon creamerymen the need of having the butter boxes made only from dry wood and asked Prof. Robertson to issue a circular to dairymen drawing their special attention to this.

Another question discussed was that of transportation. Prof. Robertson drew attention to the necessity of having cool, ventilated chambers on board ocean vessels for carrying cheese. The steamship companies had promised the government to have this done, but the active co-operation of the trade was needed in bringing home the requests to those in authority. The keeping of cheese for 24 hours in transit at a temperature of 75 degrees might not injure the quality of the cheese, but it would help to start the growth of undesirable bacteria which might eventually cause injury to the product.

Mr. J. A. Ruddick, who went from Canada to New Zealand, as dairy commissioner, last fall, has sent a letter to one of our trade journals containing some points of interest to our dairymen. We have been accustomed to look upon our sister colony on the other side of the globe as a rising competitor of ours in dairy products in the British markets, not only in regard to butter but also in regard to cheese. Mr. Ruddick points out that there is a growing market south of the equator for cheese and to use his own words:

"The present indications are that the export of cheese from New Zealand to Great Britain would not increase. Indeed it would not be surprising if the southern hemisphere took the whole output in a very short time. There is no other country south of the equator which can compete with New Zealand in the manufacture of mild, cool-flavored cheese."

While this is assuring to those in the cheese trade, what he says in regard to New Zealand as a competitor in the export butter market is not so pleasing. To quote again: "The make of butter is increasing and Canadians will have to look sharp if they expect to keep ahead of their cousins under the Southern Cross. No money is spared in the building and equipment of these factories and good salaries were paid to secure first class makers. The best factories are all fitted with mechanical refrigeration. Every few days the butter is shipped to the government cool stores, where it is graded and held at a temperature of about 20 degrees F. until it goes on the direct steamer for London."

The cheese factories and creameries here are now under full sway. From May 1st to date (May 22) our exports of cheese and butter have been twice as large as they were for the same period a year ago. There is a good export demand for all the new cheese, which is selling at the factories at from 9 to 9¼ cents, though some sales are reported at below 9c. Creamery butter also sells readily for export at from 16 to 16½ cents at Montreal, which would mean from 15½ to 16 cents at the creameries. J. W. WHEATON.

Toronto, Canada.

Cost of Raising Calves.

The New Hampshire Experiment Station has been keeping record of the cost of growing calves from the time the milk of the dam was good, up to six to eight months, when turned to pasture. The general method of feeding, which was similar to that now followed by most farmers, is given as follows:

The calf was taken from the cow as soon as the latter's milk was fit for creamery use. It was first fed with whole milk, which was gradually replaced by skim milk, until by the end of the second week of growth, it received only milk that had been run through the separator, and was almost completely free from fat. To replace the fat, a mixture of ground flaxseed, cooked in water, was added to the milk. The proportions in this mixture were one pound of flaxseed to four quarts of water, making a thick, mucilaginous jelly, which could be readily mixed with the milk.

The calves were fed from seven to ten quarts of skim milk, and one or two quarts of flaxseed jelly, daily, in two feeds. During part of the time, middlings were cooked instead of flaxseed. As soon as possible the animals were encouraged to eat grain and hay, and the increase in food, made necessary by gain in size and weight, consisted of these materials, while the skim milk and flaxseed remained nearly constant in amount as long as they were used, which was up to the age of six to eight months, or until the animal's first season in the pasture. Some of the calves were taught to drink from a pail, but most of them were given their milk through Small's calf feeder, since it made the work of feeding much less.

The skim milk was figured at 20 cents a hundred pounds, and the feeds at the price for such feeds obtaining in that state.

The following is the weekly summary of gain and cost for the several periods:

Eight calves under 5 weeks old. Average weekly gain, 7.6 pounds. Average weekly cost, 40.6 cents.

Eight calves from 5 to 9 weeks old. Average weekly gain, 9 1 pounds. Average weekly cost, 36 7 cents.

Eight calves from 9 to 13 weeks old. Average weekly gain, . 11.8 pounds. Average weekly cost, 43.1 cents.

TESTED BY THE MILK PAIL
Quaker Dairy Feed
is made entirely of grain—principally of oats—combined in scientific proportions. It is complete for the production of milk and the proper maintenance of the animal.
PROFIT.
It may be combined with great profit with all forms of home-grown feed.

The American Cereal Co.
1348 Monadnock Bldg., Chicago, Ill.
SCIENTIFIC ADVICE ON FEEDING

Eight calves from 13 to 20 weeks old. Average weekly gain, 10 pounds. Average weekly cost, 52 9 cents.

Six calves from 4 to 8 months old. Average weekly gain, 11 pounds. Average weekly cost, 63 7 cents.

Two calves from 5 to 13 months old. Average weekly gain, 5.25 pounds. Average weekly cost, 58.3 cents.

Four heifers from 13 to 16 months old. Average weekly gain, 6.12 pounds. Average weekly cost, 65.1 cents.

The heifers one, two, three and four were maintained on pasturage from July 24th, until October 26th, 1897, a period of thirteen weeks and two days. The total gain in weight of the four animals was 313 pounds, or an average weekly gain of 5 9 pounds per head.

In another bulletin it is proposed to take the same animals up to an age where they come into milk and begin to pay their way.

Paying for Butter Fat.

ED. HOARD'S DAIRYMAN:—In your issue of April 28th, is an article giving the official tests of Holstein-Friesian cows, and the amounts of butter are calculated on the basis of 80% butter fat to a pound of butter.

Is this the usual percentage? If so, of what does the remaining 20% consist?

Last autumn a stranger started a creamery here, the first in the place.

We farmers around here are mostly ignorant of dairying.

He uses the Babcock test and pays us 2½ cents less per pound for the butter fat than the price he receives for the butter.

Yamhill Co., Ore. W. E. H.

The amount of water in butter can be made to vary widely; according to the method of manufacture, it can be made to contain anywhere from 10 to 35% of water. It is therefore necessary in testing cows, to have some standard for the amount of fat in the butter made, so that the tests shall be comparable, when made at different times and under different conditions.

The Holstein Breeders' Association have adopted the plan of adding one-fourth to the weight of fat found by the Babcock test to indicate the amount of butter that could be made from the fat. This would make butter

Eureka Harness Oil is the best preservative of new leather and the best renovator of old leather. It oils, softens, blackens and protects. Use
Eureka Harness Oil
on your best harness, your old harness, and your carriage top, and they will not only look better but wear longer. Sold everywhere in cans—all sizes from half pints to five gallons.
Made by STANDARD OIL CO.

containing 80% of fat the other 20% consisting of water, salt, casein, etc.

If you are receiving 2½ cents under the selling price of the *butter* for the *butter fat* you furnish, you are not receiving enough money.

A hundred pounds of butter fat in the milk will make on an average 116⅔ pounds of butter, when all conditions are at their best, and you should be paid on the amount of butter manufactured.

As it is now, you have decidedly the small end of the bargain.

Making Butter in Winter.

Demonstrated to Be Practicable and Profitable.

Professor Robertson says in his report:—Although it seemed evident that butter making at creameries in Canada during the winter was a business which could be developed with profit to all concerned, there were difficulties in the way of getting it established. Some objectors said that it was not practicable because the roads were bad during the winter, and milk or cream could not be delivered regularly. Others said that the weather was too cold and that the cows could not be kept in milk satisfactorily. Others said that the cows would be so weakened by being milked during the winter, that summer dairying would be much injured. It was also alleged that the cream and milk would become frozen, and thus the quality of the butter would be greatly injured. It was evidently necessary, if the business was to be established, that it should be demonstrated on a comparatively large scale, whether it was entirely practicable, and whether it could be made satisfactorily profitable. The two dairy stations at Woodstock and Mount Elgin, Ont., were established to settle these points. Practical experience seemed to be the only means of meeting the objections. I was able to say after an experience of three years in the management of those winter dairy stations that we had not found a single obstacle that could not be overcome by good management. Cold weather is a suitable time for making good butter. Even without artificial cold storage, it does not spoil readily then. I had some cream frozen solid and afterwards had butter made from it, and it was quite as fine as any that was produced. I took samples to be examined by the members of the Butter and Cheese Association of the Board of Trade of Montreal, numbered from one to nine, and let the experts say which one was the best. They picked out sample No. 9 as the finest of them all, and that was the one made from cream which had been frozen as a test. When cream has been frozen it is usually necessary to add a fermentation starter to it, and to ripen it in the usual way for about twenty hours before it is churned

The average prices realized by farmers who supplied milk to the dairy stations in 1893-94 were as follows:

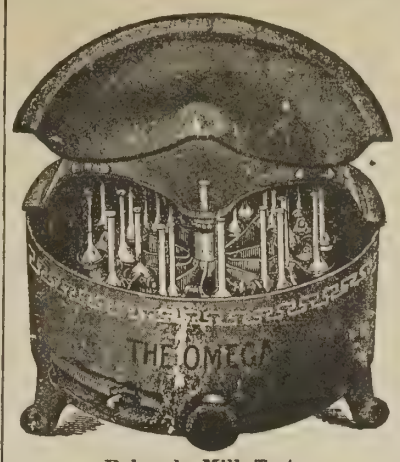
	Per Cent of Fat.	*Net Value per 100 lbs. of Milk.* Cents.
Mount Elgin	3.86	91.6
Woodstock	3.68	85.0
Wellman's Corners	3 83	93.0

	Highest	*Lowest*	*Average Price Realized for Butter.*
Mount Elgin	$1.19	63c	24.23 cts.
Woodstock	0 95	79c	24.42 cts.
Wellman's Corners	1.25	73c	24.94 cts.

Spraying Wild Mustard.

The following account of experiments carried on in England, for the destruction of wild mustard, or "charlock," are of unusual interest.

Charlock is one of the most pernicious weeds that infest farm lands, and if the simple method described below, will destroy it, it will save many dollars to the farmers of the country.



Land which is now overrun and worthless, can be brought into cultivation again and be a source of revenue instead of an eye sore.

The statement that thistles are also blasted by the solution used, is of interest. It may furnish a solution of the Canada thistle problem. We suggest that farmers who are plagued with the Canada thistle, try spraying them. The solution is cheap and not poisonous:

The following is a brief account of an experiment conducted last year by Mr. Ovens, of Torr, on behalf of the Lancashire County Council, in a field badly infested with charlock. Professor Campbell, under whose direction the experiment was conducted, could not find a field badly enough infested in the County Palatine, but Mr. Ovens was, unfortunately, able to supply the deficiency in a very marked degree.

The field selected was under oats after lea. A portion containing 110 square yards was reserved for spraying, and another portion, of equal extent, was left unsprayed for comparison with it, and the remainder of the field was gone over with a "charlock" weeding machine. The spraying took place on the 14th of June, when the oats were fully twelve inches in length, and the material used was a solution of sulphate of iron, diluted to 13 per cent. A remarkable result was obtained. The "charlock" was totally destroyed, and in a few days the contrast between the two plots was striking to a degree. Where the spraying has been performed the field bore a dark green hue, while the unsprayed plot was quite yellow, with charlock in full flower. This is conclusive enough as regards the destruction of the charlock, but the important question remains. What effect had the spraying upon the oats and the clover? It is satisfactory to find that the answer here is equally conclusive. The oats were practically uninjured, and the result in the harvest was equally good, for the binder got around the sprayed plot without a hitch, while in the other it was being choked at every round on account of the luxuriant growth of the charlock.

Another experiment was carried out in an oat field sown down with clovers and rye grass, and the effect upon these plants is the question raised by our correspondent. Naturally one fears that what destroys charlock may destroy clover, but, so far as the Torr experiment is concerned, this does not appear to be the case. The spraying in this second trial took place when the oats were about 14 inches in length, and two plots were selected—the one getting a 15 per cent and the other a 20 per cent solution of sulphate of iron. In both cases the charlock was exterminated, and the clovers at harvest were found to be as luxuriant on the sprayed as on the unsprayed plots. Another satisfactory feature of the spraying was its effect on thistles. These in every case were blasted, and in the case of the plot subjected to the 30 per cent solution, effectually made harmless. As the result of what he saw in these experiments, Professor Campbell has every confidence in recommending farmers to adopt spraying with sulphate of iron in doses of a 10 per cent solution for the general extermination of this most troublesome weed.—*Scottish Farmer.*

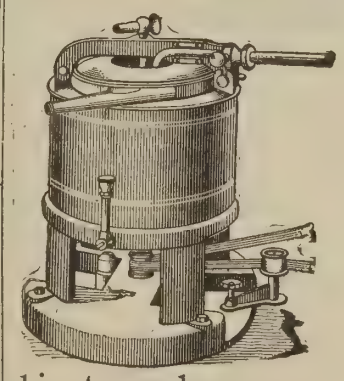
Don't Stand in Your Own Light.

Perhaps you intend to buy a binder or a mower this summer, and it may be that you have concluded that a cheap machine will answer your purpose. This means that you are **standing in your own light.**

It's better to investigate. There are some things that you should think about before putting your dollars into so expensive a machine as a binder or a mower.

Here are Some Pertinent Facts. Think About Them.

Last season the sales of Deering harvesting machines were 50,000 greater than in any previous year.



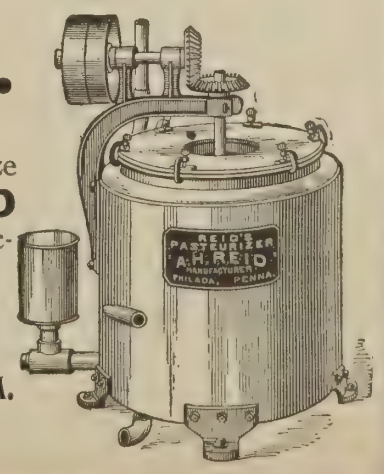
The area of ground covered by the Deering works is 62 acres—twice as large as that of any other reaper plant.

6500 employes are engaged in turning out the Deering product for 1899—more than three times the number at work in any other reaper plant.

During the busy part of last season Deering machines were built at the rate of one every 27 seconds.

Don't stand in your own light. Think about these things; they mean something. They mean that Deering machines are the lightest in draft, the easiest to operate and the most reliable and durable grain and grass harvesters manufactured.

DEERING HARVESTER CO., - - Chicago.



A SOURCE OF SUCCESS.

The greatest help to success that a creameryman can have, is the **Reid Long Spindle Separator.** It will make more money for him than any other Separator and save as much as other separators make. It will enable him to produce more cream, of finer quality, at lower cost. The most perfectly, simply, strongly and durably built skimming machine, requiring but half the power usually used, is the

Cost of Butter and Milk Production.

[Address delivered by Prof. T. L. Haecker Before the Minnesota State Agricultural Society.]

It has fallen to my lot to carry on a series of experiments covering some half dozen years with a view of ascertaining the cost of milk and butter production with cows of different breeds and types. In summing up the results of this work I am forced to the conclusion that the subject of rational feeding is, for the time being, of greater importance to the average dairyman than is that of breed or type. Had the work been carried on for only two or three years and feed stuffs during that time ruled comparatively high, my conclusions would have been different. When I find that by proper feeding under present conditions almost any kind of a cow will return a good profit in the dairy, and that the average cow in Minnesota is returning in dairy products a sum barely equal to the market price of the feed simply because of a lack of understanding of how to feed; and when we consider how many common cows there are in the state whose product might be doubled by better methods, we can readily understand how much more important it is that the kind we have be properly fed than to point out by experimental demonstration what we might realize by feeding the kind we haven't got, but should get. It has been clearly demonstrated that cows bred specially for the dairy make a much larger return for food consumed; but our dairy farmers, unfortunately, have not many of that kind, and to change them will require years of careful selection and breeding. It is, therefore, of primary importance that farmers first learn to make the best of what they have. During the past few years I have received reports from many of our creameries giving the estimated number of cows contributing milk, pounds of butter made, receipts for butter, expense of manufacturing and amount paid to patrons. From these reports it appears that the average gross return to the farmer per cow is only about $22. During the years 1896 and 1897, the time covered by the reports, it cost us at the experiment station on an average $20.14 per year to feed our cows that would be classed as common cows, charging local market price for feed. It, therefore, appears that the ordinary cows, as ordinarily kept on Minnesota farms, receiving $15 worth of feed per year, return for butter fat only $7 annually over the market price for the feed consumed.

Taking the records of all the common cows that were in the station herd during the two years, we find that they made a gross return for butter of $44.53, valued at 15c per pound, being about the average that farmers received during that time. Since these cows are no better than the average cow of Minnesota, it is but fair to conclude that the $22.53, which our common cows returned in excess of that received from those contributing to Minnesota creameries, is wholly due to a lack of knowledge of proper feeding and care.

The statistics referred to also show that there are in round numbers 435,000 cows that are contributing milk to Minnesota creameries, and bringing a gross return for butter of $9,570,000, and, if these cows received proper feed and care they would bring in a gross return of $18,340,000, being a gross loss, because of improper feeding and care, of $8,770,000. I estimate that by an additional $5 worth of the right kind of feed, together with comfortable housing and regularity in feeding and milking, this enormous loss could be saved to our farmers. The $5 worth of extra feed would amount to $2,175,000, which would leave a net increase of over $6,595,000 as compensation for the extra feed and care.

I have in these calculations taken into account only the cows that are contributing milk to creameries, because we know scarcely anything as to what the others are doing. Of those there are some 300,000 in the state, and assuming that they, too, are returning $22 per head less than they would return with good feed and care, we have an additional loss of $5,100,000. In view of these enormous losses because of a want of knowledge of the science of feeding, is it any wonder that I am forced to the conclusion that under present conditions the feeding problem is the most important one that we have to deal with?

The error that our farmers are making is not so much in underfeeding as it is in not providing their cows with the right kind of feed. This fact was very clearly demonstrated in a letter from a dairy farmer stating that he was feeding good millet hay, all they would eat, a bundle of unhusked corn, averaging about ten ears to the bundle, and five pounds of roots. In examining the chemical composition of the food stuffs and the quantity given, we find that the cows were receiving all they could eat.

A cow fed with such a ration is to all external appearance well fed. But when we examine the amount of protein provided by this ration, we find that for a milch cow she is only half fed. Cows require of the group of nutrients known as proteids, from two to two and one-half pounds per day, according to the amount of work they are doing. This ration furnished only .98 of a pound, being only a trifle over what is needed daily for bodily maintenance. An animal weighing 1,000 pounds, kept quiet and comfortably housed, needs .65 of a pound of protein per day for rebuilding the body tissues that break down daily, so there was left available for milk or meat only .33 of a pound of protein, or about enough to make a pound of gain, or to produce the amount of milk required for half a pound of butter daily. This is not an exceptional case, but it is a fair illustration of the almost universal practice among farmers. That such is the case is confirmed by the statistics referred to, which show that the average cow yields only 165 pounds of butter per year. Allowing half a pound a day during 300 days, which is the time ordinary cows are expected to give milk, we have 150 pounds per cow. The 15 pounds additional for which statistics give her credit is made up during the short period in the spring when she is in good pasture.

Great efforts have been made to introduce improved stock among our farmers; so far these efforts have received but little encouragement on their part. Unless they understand the principles of feeding and have acquired the habit of taking proper care of improved strains of live stock, there is little use in placing such in their charge even as a gift. They must first learn how to properly feed and care for common stock before they can expect to do justice to a full blood, which universally requires more skillful handling than does the common animal. Improved stock is made such by skillful breeding and feeding, and if the best representative of its kind is placed in charge of a person lacking knowledge and skill in feeding and breeding, reversion quickly follows and the farmer concludes that after all common stock is best adapted for him.

The first step toward substantial improvements in feeding is to show the enormous and unnecessary losses that our cow owners are annually incurring for want of knowledge on this subject, which will create a desire to learn improved methods. This should be followed by furnishing literature containing tables giving the comparative value of feed stuffs, thair chemical composition, and average content of digestible matter, the uses that are made of the different nutrients, with plain instructions for compounding balanced rations, and best methods of feeding and caring for the herd. This information is needed, not only by every creamery patron, but by every farmer in the state who owns live stock.

The real feeding value of our different kinds of food is little understood by the average farmer. The market prices for the different grains and mill products are based upon supply and demand, and not so much upon their feeding value. Farmers, as a general rule, know that bran is good food for dairy cows; they also know that corn, oats and barley are good, but they do not seem to understand why a mixture of such excellent feed as corn, oats, barley, will not produce as good results as can be secured by feeding bran and oil meal in connection with them. The reason is plain, when the needs of the animal system and the composition of the different kinds of feed are known.

In feed stuffs there are three groups of substances which must be considered in formulating a ration to secure best results. These are known as protein, carbohydrates and fat.

Protein is the name of a group of materials containing nitrogen. On account of the presence of nitrogen this group is sometimes called the nitrogenous group, in opposition to the constituents of feeding stuffs, the carbohydrates, fat and ash, which are non-nitrogenous. The function of protein is to furnish materials for the formation of lean flesh, blood, tendons, nerves, hair, horns, wool, and of the casein and albumen of milk. For the formation of these materials protein is absolutely indispensable. It is important to remember that no substance free from nitrogen can be converted into protein or be used as a substitute for protein. It is, therefore, necessary for an animal to receive a certain amount of protein in order to maintain existence, grow or produce milk.

Carbohydrates are made up of several substances, usually divided into two groups—nitrogen-free extract, including starch, sugar, gums, etc., and crude fiber. Coarse fodders contain large amounts of crude fiber, while most of the concentrates contain little fiber, but are rich in starch and sugar. Carbohydrates are either stored up in the body as fat or are burned in the system to produce heat and energy.

Fat, or the material dissolved from a feeding stuff by ether, and for this reason the group is often designated as ether extract, includes the fats and the green coloring matter of plants. The fat of food is either stored up in the body or burned to furnish heat and energy. As a heat producer a pound of fat is worth as much as 2.25 pounds of carbohydrates. When fat has been multiplied by this factor, the result is called fat equivalent.

A cow, or in fact any mature animal, can use only from five to seven pounds of digestible carbohydrates and fat equivalent to one of protein. If we feed more carbonaceous matter without increasing the protein there will be an abnormal shrinkage in the flow of milk, because the increase will cause the animal to commence laying on fat. If the ratio of protein to carbohydrates and fat equivalent is narrowed down the animal will need more heat than the carbohydrates and fat can supply, and it will consume some of the protein to make up the deficiency. It follows, therefore, that for the best results

Write for what you want. Visitors always welcome JOHN E. ROBBINS,
Greensburg, Ind.

the two groups of nutrients—protein and carbohydrates—must be fed within the limits stated.

But all our ordinary foods, both in grains and roughage, contain carbohydrates largely in excess of an animal's needs, and mix the grain and roughage grown on the farm as we will, it always follows that we are short in protein or have too much of carbohydrates. In fact, all the nutrients needed by our farm animals are found in all our farm food stuffs in great abundance, except that of protein. In marsh and prairie hay, in timothy, millet, sorghum, fodder corn, stover and straw, there is more digestible carbohydrates than cattle can make use of. The same is true with all our grains. In compounding rations from farm crops we always find it necessary to resort to some mill products, containing a high percentage of protein to make good this shortage, except in cases where clover hay and alfalfa are available.

Since the supply of water, ash, carbohydrates and fat is always in excess of our needs, and being practically as free as water, air and light, it follows that they lose all the commercial value, leaving digestible protein the measure of value of our food stuffs.

A ton of bran costs $10. It contains 238 pounds of water. It would be foolish to place any value on the water when there is plenty of it at home in the well. It contains 116 pounds of ash, 58 pounds of indigestible protein, 1,258 pounds of carbohydrates and 80 pounds of fat. It would be absurd to pay at the rate of $10 per ton for these materials when we have more at home than we have any use for. So the logical conclusion is that the $10 are paid for the 250 pounds of digestible protein. When bran is used in the ration, hay can be fed as roughage, but I cannot make corn stover a part of the ration because it contains too little protein and too much carbohydrates, and in order to be able to feed stover, mill stuffs containing a higher percentage of protein must be purchased, which decreases the value of stover in proportion to the extra amount of protein that must be purchased. Or, in other words, stover is worth as much less as its protein content is less than that in the hay. When no hay is available and stover or corn fodder must be fed, it will be necessary to resort to oil meal.

A ton of oil meal contains 184 pounds of water, 114 pounds of ash, 72 pounds of indigestible protein, 886 pounds of carbohydrates and 158 pounds of ether extract or fat. Surely no sane person would be guilty of buying these substances and paying at the rate of $20 to $25 per ton, when he is already overstocked with them on the farm. So it must be that he is buying the digestible protein, which is the only nutrient lacking. The ton of linseed meal contains 586 pounds of digestible protein, and, since the cost of this nutrition in bran was 4 cents a pound, the value of the ton of oil meal is $23.44, when it contains 29 3 per cent digestible protein, and $22 08 per ton when it contains 27.6 per cent digestible protein. The wider the nutritive ratio of food stuffs the more protein must be bought to balance the ration and the less money value those food stuffs have.

If I find any farm grown feed that contains enough digestible protein so that it will not be necessary to purchase any mill products, then that feed is worth to me as much more per ton as I would have to pay for the difference in protein, if the farm feed contained a lower percentage. Or, in other words, the money value of all the feed stuffs used in the ration depends upon the percentage of digestible protein they contain.

When bran can be purchase for $10 and oil meal for $22, I can afford to pay only 21 cents a bushel for corn, 12 cents for oats, 18 cents for barley, for I can get the only nutriment that I need at these prices in bran and oil meal. If farmers will bear this in mind, they will not feed 35-cent corn, 30-cent barley, or 25-cent oats, when shorts can be purchased for $8, bran for $10 and oil meal for $22 per ton.

Another mistake generally made is in buying shorts for dairy cows instead of bran; presumably because shorts are heavier feed. A ton of shorts contains 236 pounds of water, 92 pounds of ash, 98 pounds of indigestible protein, 1,284 pounds of carbohydrates and 90 pounds of fat. As above stated these substances we have in great abundance on the farm; as the digestible protein is the nutrient needed, it follows that the 200 pounds of digestible protein in the ton of shorts fixes their value, and since we can get it in bran, or oil meal at 4 cents a pound, shorts, when containing 10 per cent of digestible protein, are worth only $8 per ton for dairy cows, when bran is worth $10.

We find the same inconsistency exists in regard to the market price of roughage. Take, for example, timothy hay, and assume that it yields two tons per acre. In two tons there are 136 pounds of digestible protein, which, at 4 cents a pound, amounts to $5.44 worth of protein per acre, making its feeding value $2.71 per ton. This hay sells in our market for from $4 to $8 per ton. An acre of clover will produce about two tons of cured clover hay, containing 304 pounds of digestible protein, which at 4 cents a pound amounts to $12.16 worth of protein, making its feeding value $6.08 per ton. An acre will produce six tons of fodder corn containing 312 pounds of digestible protein, which at 4 cents a pound makes $12.48 worth of protein in six tons of fodder corn worth $2 08 per ton.

In view of these discrepancies between ruling market prices and the actual money value of feeding stuffs, we have for several years disregarded prices of feed and have based our calculations on the cost of digestible protein and have fed it in whatever palatable form we found it the cheapest. It is by this method and partially through the decrease in price of protein that we have reduced the cost of producing a pound of butter from 10.6 cents in 1893 to 5.4 cents in 1897.

The profit in dairying, as in any other business, depends upon the margin between the product and the cost of production, and, it is, therefore, of primary importance to provide feed stuffs at the least cost, and when grain is relatively high it may become necessary to discard our farm grains entirely, sell them, and buy mill feed. This winter we are feeding ten parts of bran to two parts of oil meal, and use fodder corn exclusively for roughage. The standard ration is ten parts of the bran and oil meal mixture, to fifteen parts in weight of the cut fodder corn. The cows are fed all they will eat up clean, but the proportion between the roughage and the grain is always maintained—once and a half as much roughage as grain. The reason cows are fed all they will eat is because we must first provide the food of maintenance and the more they will eat over and above this, the more will they have available for converting into milk and meat. Each cow is fed twice a day; half the grain feed and roughage in the morning, and half in the evening. That generous feeding pays is clearly illustrated in our record for the five years ending December 30, 1897. During the years 1893, 1895, 1896 and 1897 cows were fed all they would take, while during the year 1894 they were fed light.

	Milk.	*Butter.*	*Cost of one lb. Butter.*
1893	6,407	364	10.6 cents.
1894	4.909	271	10.9 "
1895	7,418	352	8.0 "
1896	7,454	349	6.3 "
1897	6,962	351	5 4 "

These are averages of the entire herd and show that during the four years when receiving all they would eat up clean they averaged 354 pounds of butter each, while the average yield for the year 1894, when on comparatively light feed, was only 271 pounds. The cost of production was also the greatest that year. The kind of feed has little, if anything, to do with the yield, so long as they get the required amount of nutrients in the right proportion, and in palatable form. We get as much out of fodder corn as we do out of ensilage, and as much from a pound of protein in bran as we get in any other grain. They give just a trifle more milk when receiving some succulent food, such as roots and ensilage, but practically the same amount of butter or other milk solids. We select the cheapest foods and so mix them that the cow gets one pound of digestible protein to six of carbohydrates and fat equivalent. If we should feed a wider ration, that is, one that contains more carbohydrates and fat equivalent than the amount above stated, she would gradually lay on fat, shrink in milk and failure to breed would likely soon follow. But when the above mentioned nutritive ratio is maintained no such difficulties are encountered.

Our records show that changes in feed during the winter are objectionable, as changes always cause shrinkage in milk. A more uniform flow is maintained by feeding the same ration all winter, if possible. If it becomes necessary to make a change, it should be very gradual, so the system can adjust itself to the variation in bulk, and the muscular action required by the stomach to digest that particular ration.

A daily outing should be given to the herd in a covered run way during cold weather and in the open yard during pleasant days. Sunlight and fresh air are indispensable with a dairy cow, but she should not be compelled to remain outside if she is uncomfortable, as comfort and contentment reduce the amount of food required for bodily maintenance and increase the amount available for dairy products.

Strict uniformity in feeding, regularity in feeding and milking, are just as essential as providing the proper kind of food. Salt and water should be accessible at all times, and the latter should not be at a lower temperature than 60° Fahrenheit, because if the water is colder they will not drink until they become exceedingly thirsty, and then drink more than they should take at a time

Freezene.

ED. HOARD'S DAIRYMAN:—May I say a word in regard to freezene, about which you gave us a good word of warning, April 14? I would like to say that I was given a sample to try by the father(?) of the two enterprising boys that discovered it, (so he claimed) with specific instructions how to use it to get results claimed. I followed these closely for two reasons, first to find if it would do as they claimed, and also to determine whether it would increase the acidity of milk embalmed with it, which he claimed it would not with the acid test taken very carefully. I discovered it increased the acidity of the sample of milk in which I put it, .5 of 1% more than a sample of same milk with no freezine in it, both samples being taken care of in best possible manner, and used exactly alike. I should like to meet the gentlemanly father spoken of above to claim wager made on the two opinions. Hoping you will still keep on with the good work of exposing such frauds and dangerous humbugs,

I am truly yours for dairy improvement.

Fort Wayne, Ind. H. R. H.

HOLSTEIN CATTLE! The Choicest Milk and Butter Breed in the World. Write to Wis. Live Stock Ass'n, Appleton, Wis., U.S.A.

SHADY NOOK HERD Holstein-Friesians Two yearling bulls from dams giving 60 lbs. and 71 lbs. each. Test 4.5 and 3.6 each. W. R. GATES, Ripley, Jefferson Co., Wis.

HOLSTEIN-FRIESIAN BULL CALVES From advanced registery and officially tested, prize-winning dams, as high as the 21-lb. class, 70 to 76 lbs. milk from cows. Quality as well as quantity. If you want *the* best address MALCOLM H. GARDNER, Darien, Wis.

130 Holsteins. First prize herd at Trans Mississippi Exposition, at Omaha. 1st and 2nd on aged cows and 1st on two-year-old heifer in the seven day butter test, open to all breeds at same Exposition. Three cows in this herd have produced the most butter in seven days of any cows ever officially tested. A score of others nearly as good. Our richest bred bull calves are taken young. Sons of De Kol 2d and Netherland Hengerveld head the herd. Animals of both sex and any age for sale. Write stating just what you want, HENRY STEVENS & SONS, Lacona, Oswego Co., N. Y.

We offer you the **Superior Bred** **HOLSTEIN BULL**
Mechtchilde, Sir Tirania 2d.
Dropped Nov. 12, 1898.
He is sired by a son of Tirania, Sir Mechtchilde who sold for $4800 00 His dam, Tirania, won the National Butter Prize in competition with 73 cows from 12 states, and sold for $1500 00. She has a milk record of 91 lbs. in one day, and a butter record of 36 lbs 11 oz. in 7 days, and his sire's dam, Mechtchilde, sold for $2500.00, and has a milk record of 112 lbs. in one day, and a butter record reported at 39 lbs. 10 oz. in 7 days. In his veins also flows the blood of Castine, winner of the International Butter Prize of $1000.00, at Buffalo, and also winning the 30 days state butter test at Ohio, making as a 4 year old, 98 lbs. 10 oz.; also of Onetine, winner of the National milk test at Rotterdam, Holland; also of Mercedes, winner of the Breeder's Gazette Challenge cup 30 days butter test, defeating the celebrated Jersey cow, Mary Ann, of St. Lambert, and producing 99 lbs. 6½ oz. of butter. Her son Jacob sold for $5000.00 and her daughter, Mercedes 3d., sold for $4200 00 when 8 months old. In short, there are 17 cows in his pedigree that average over 100 lbs. of milk in 1 day; 35 cows in his pedigree that average over 90 lbs. of milk in 1 day; 8 cows in his pedigree that average over 30 lbs. of butter in 7 days. If you want him speak quick. Price $65 00. **WISCONSIN LIVE STOCK ASS'N, Appleton, Wis.**

A GREAT RISK
For dairymen is in using as head of their herds cheap bulls. Do you know that the bull is half the herd? You may have a handsome appearing animal, but lacks in that of the most important, breeding. Only inherited dairy qualities breed on. **Valley Mead Farm** has sent out bulls to head the best herds of Holsteins in the country this spring. Thus a fact which goes to prove that the bulls bred at "Valley Mead" have no superiors in the world. A bull costing $100 is one we recommend. Start in now. Organize a company if you can not afford one alone. Address
Valley Mead Farm, Monticello, Wis.

Markham Manor Farms. Simonsville P. O., Andover, Vt.
Holstein-Friesian cattle bred from the most fashionable butter families, individually large producers, and of the most approved show form. FRED TSCHUDY & SON, Monroe, Wis

THE MAN AND THE COW.

Prof. Markham, of San Francisco, poetizes the "Angelus" that celebrated painting by Millet, under the caption, "The Man and The Hoe."

Editor Watson of the Western Creamery, a bright California production, relieves his vexed soul from the annoyance had with half drunken Italian milkers by the following entitled, "The Man and The Cow."

Bowed upon the one-legged stool he sits, his gaze fixed on the pail,
The emptiness of which he seeks to fill with milk commingled with the earth.
Who pays him, thus to sit and stare and draw the milk
With steady pull from short-horn cow, a sister to the steer?
Who brings this milker from his native Alps and garnishes his breath
With wine and leeks to scent the morning air?

What's HOARD'S DAIRYMAN or *Western Creamery* to him?
What cares he if the snowy peaks of Italy or the far western hills
Beyond the Sierras, supply the pigment for red'ning of the nose?
For 'tis the red juice of the grape; sour and to his taste.
All lands and climes are alike to him, and life is one long,
Sweet booze, and milking but an incident.

Invent, O mind and imitative faculty! Build us some inanimate, pulsating thing
Which imitates the hand in milking, less inclination to hold aloft the wine.
Give back to us the lacteal fluid as nature made it in her laboratory,
With due proportion and free from soil and alcoholic beverage.
Milk, earth and wine are good, each in its way, though often spoiled
In combinations which individual men abominate.

The weight of centuries has not bowed us down. Nor are we brothers to the ox
We climb the peaks of song and watch the rift of dawn,
While the reddening of the rose is in our line.
We have no masters, lords and rulers in our land to hold accountable
For immemorial infamies and wrongs. O exile from the Alps!
Thy habits, tastes and customs are not ours, and we're glad of it.

FARM INVESTMENTS.

There lived in Wisconsin, several years since—he has now gone to his reward—one of the grand old stock of American farmers. He was every inch a farmer from the ground up. First, he was a great reader and student of farm literature. Everything he could get that would throw light on the mysterious processes of nature with which he had constantly to deal, he would buy and read.

Second, he was an energetic man of business with a good financial head. He amassed a fortune of $100,000 in 28 years, in straight farming, and never did what might be called a full day's work, owing to physical weakness.

It was always our delight to get into conversation with this man, and draw from him his ideals and standards of farm judgment. He was a powerful reasoner on all farm questions, whether relating to live stock, cultivation of the soil, preservation of fertility, or the more favorite subject with him, of farm *improvements*. On this subject we remember well his observations one day, which were as follows:

"If I go to any of my neighbors who are out of debt, and inquire what is their ideal or ambition in regard to their surplus money, I find it is to loan it to some other farmer, put it out at interest, and own a mortgage on some other man's farm. That is the height of their ambition. I believe this is a great mistake. The effect of it is to skin the farm in the end, to get money to loan. It also lowers the grade of their farm ambition.

The minute a farmer gets to be a money loaner, he ceases to be an enterprising, progressive farmer. A note and mortgage is the end of his ambition.

A much better and broader policy is to loan the surplus money back to the farm. Put it into permanent improvements. There is a field here that needs tile draining; another that needs some money expended in getting rid of rocks and bothersome stones. Better buildings and stables are needed. Some money should be expended each year, in introducing better blood into the horses, cattle, sheep and swine of the farm, so that they are consequently kept on the *up grade*. It is a matter of economy to have the best farm machinery and good sheds to store them in.

Then there is the question of labor. Most farmers are afraid to hire what help they need. Not one in ten goes through the year with help sufficient to do his work well, in the right season, and with the best economy. Consequently he is wasting results at every turn.

A wrong philosophy prevails; it is not based on sound business sense. My idea is that every farmer ought to work for a good bank account, so as to have money enough to lend to the old farm every year, to improve it and make it more productive and profitable. That policy will make the farm rich; it will make the farmer grow larger instead of smaller.

I never yet saw a farmer fail, that put back on the farm, every year, all of its surplus earnings, over and above a reasonable sum for the support of his family.

On the contrary, such farmers are the ones who buy out their neighbors. I love to see a farmer who is a growing man."

Green Feed for Cows.

"Last winter we kept two cows and made only enough butter for home use," said an acquaintance to me recently. "This winter we have only one cow and have made more butter than we could use. We have sold $15 worth since cold weather began."

"That shows the difference there is in cows," I replied, quickly. (Difference in cows is a hobby of mine).

"No it doesn't—not this time," said the man, "for the cow we now have is one of the two we had last winter. It does show something, however, that would have been worth a good deal to me if I had known it twenty years ago. It shows the value of feeding rightly."

"But you have always fed liberally."

"Yes, liberally enough, but not rightly. When I was in the dairy business I put too much faith in grain and other dry feed. Ground feed—a mixture of corn, oats and wheat bran—was my hobby, with plenty of that and a supply of good hay, clover and corn fodder. I thought I could do all that was possible for the cows. Now I've learned differently. This winter our cow has not had an ounce of ground feed. Instead of grain I have given her garden roots, pumpkins and squashes. I had tons of such stuff on hand last fall that I couldn't sell and didn't know what to do with. (You know I did some truck gardening last year.) About that time I came across an article in my farm paper, telling of wonderful results from feeding roots to cows. It sounded like a big yarn, but I thought I would make a trial anyway and get rid of the stuff on hand. Well, I went a little slow at first to get the cow used to the change, but during most of the winter I have given her a twelve-quart pail full three times a day. The result I have already told you."

"People complain of winter churning and say the butter doesn't come," he continued. "But our butter comes now just as easily as it did in summer. And the butter is extra good, too. I tell you, a man can make June butter in midwinter if he will only feed plenty of green stuff to his cows."

The man's conclusions were pretty nearly right. My own experience has been much like his. No one can realize the value of a liberal feeding of root crops to milch cows until he has made a trial of it. However, I would not let the roots take the place of grain altogether, as my friend did, but would give a liberal feeding of both every day.—W. H. JENKINS.

There are two points prominently brought out in the above.

1. The importance of making a study of this feed question, so that we may know how to feed rightly.

With a cow as with a threshing machine, a man can waste results greatly, if he does not know how to feed rightly. It is because HOARD'S DAIRYMAN believes in this that it places such stress upon the balanced ration. It saves waste.

2. The value of succulent food for the cow in winter. Here is where the silo comes in with so much force. It is worth while to think well and long on these two points.

Sample Oleo Fraud.

Customer Given Substitute but Charged for Choicest Butter.

An incident has come to the knowledge of *The Star*, of Washington, D. C., which indicates that imitation butter frauds are still practiced in that city despite all the exposures and the attempts at prosecution. A housekeeper for two years past has been buying at a certain establishment a particular i

line of what she believed to be pure butter of the best quality. She invariably paid the highest price currently commanded by the choicest butter. She always asked for this same commodity and received it unquestioningly. After many months, something about the "butter" aroused her suspicions, and she submitted a sample of a recently purchased quantity to a chemist, with the immediate result that she was told she had been buying an ordinary grade of oleomargarine. Indignant at the fraud, she went at once to the dealer and protested, whereupon the dealer blandly told her that of course she had been buying imitation butter all the time and that he had supposed she knew what she was getting.

This impudent defiance of the law was the more flagrant because of its frank confession. It is apparent that the purchaser did not know she was getting imitation butter, because she was willingly paying a price that she knew to be at least fifty per cent higher than that usually commanded by oleomargarine. Had she wanted the imitation and bought it, she would have paid the lower sum. Such cases ought to be taken immediately into court and prosecuted. It is unfortunate that the legal processes have thus far been so slow in their punishment of the miscreants who practice this fraud. Aside from any question of the wholesomeness of the fake product, the moral iniquity of the transaction warrants the severest penalties. Housekeepers must evidently be on their guard at all times, for it is plain from the incident just related that the frauds are still in progress —*Chicago Dairy Produce.*

Paraffine in Oleomargarine.

Not content with forcing upon the public an article so strongly in imitation of butter as to become a fraud, some of the manufacturers of oleomargarine are now adulterating their product with paraffine. Slight traces of this substance have been found from time to time, but some of the recent analyses of commercial oleo have shown nearly ten per cent of this wax.

Prof. Geisler, chemist for the metropolitan district of the New York State Agricultural Department, has just completed a very careful analysis of a sample of oleo taken from one of the retail grocery stores of this city by Assistant Commissioner Kracke, and the results of his investigation are astonishing. From a sample of a trifle less than one ounce of oleo there were extracted 40.88 grains of paraffine. This is so close to 10 per cent, that in a 60 pound tub there would be about 6 pounds of this tasteless but exceedingly objecticeable matter.

It is a well known fact that paraffine is absolutely indigestible, that it resists the action of nearly all acids, and that 105 degrees of heat are required to render it liquid. The best medical authorities in the country agree that the introduction of such a substance into the human stomach is dangerous to health, and the laws against the adulteration of food products in that way should be most rigorously enforced.

It is time that the unscrupulous methods of the makers of oleomargarine were more thoroughly aired, and that an unsuspecting public should receive greater protection from this gigantic fraud.—*N. Y. Produce Review*

Fencing the Bull Lot.

ED. HOARD'S DAIRYMAN:—Seeing an inquiry in your issue of May 12th, in regard to fencing the bull lot, I will describe mine. It may benefit someone else if not the one that made the inquiry.

I have a shed on the east side of my barn containing two box stalls, and a yard leading from each stall for two Jersey bulls. The doors are left open except in severe weather, so they go in and out at will.

We went to the woods and cut poles six or eight inches in diameter, and about eight and one-half feet long, put them in the ground two and one-half feet, leaving six feet out. To these posts we wove a three strand, riven, picket fence four feet high. On the inside of the pickets and posts, we stretched five strands of barbed wire, and on the two feet of posts above the pickets, stretched three more strands of barbs making in all, eight strands of barbs. Of course, on the fence dividing the two lots, the barbs would have to be on each side of the pickets, making thirteen strands of barbs on that string of fence.

One of my bulls is very mean, but he never bothers the fence nor tries to get to the other bull. I like this better for myself, than a tight board fence. C. H. H.

GOOD ADVICE TO BREEDERS.

Every man who handles or breeds stock, be it grade or pure bred, should read and consider carefully the introduction to the report of the Kansas Stock Breeders' Association, by Secretary Coburn. He says:

"My little introductory is the result of thirty-three years of acute observation, and is as good as I can write."

And then continues as follows:

The mistake which keeps many a breeder down to or below the plane of mediocrity in business, is his failure to start with the right ideal and stick to it. The active years of any ordinary man's lifetime, are sufficient for his acquiring fame, if not fortune, as a specialist in at least one breed of animals, if he starts right, breeds right and feeds right. Success in its best sense will not, however, be likely to attend him if in that time he often changes breeds or ideals. It is the fixed, determined purpose that will bring him to the desired goal, and without this it is never reached. Bakewell, the Collings, and Cruickshank had it, and their names are revered wherever improved stock is known or appreciated. The man who breeds trotters this year and crosses them with Clydesdales next year, simply because draft horses seem to be in better demand, or breeds his Jersey cows to Hereford bulls, to meet the call for white-faces, will acquire neither honor nor riches. It is a great thing to excel, even with one breed; few men ever permanently succeed with more, and thousands who mean well, try, only to fail, because they are not equal to properly handling any, through lack of the essential genius.

In breeding, as in character-building, a day or a false move may mar what has cost a lifetime or a fortune to make. To the beginner I would say, deliberate long in the selection of a breed and an ideal; having once adopted them, persevere to the end in the work of their better development, regardless of changing fashions or fluctuating markets. In other words, don't scatter and don't wabble.

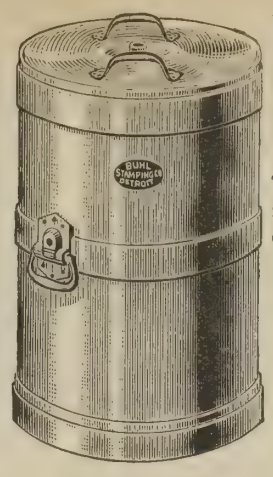
The breeding highway is strewn with the wrecks of those who had too many purposes and experimented with too many breeds.

Malt Sprouts.

ED. HOARD'S DAIRYMAN:—C. E. B., Denver, Colo., inquires concerning the feeding value of malt sprouts for dairy cows.

This by-product of the brewery is rich in both protein and ash materials, while its carbohydrates run about the same as bran. From a chemical standpoint, therefore, it is a very valuable feeding stuff, while experience shows that cows are not fond of this food and do not readily take to it if given in large quantities. If of good quality and fresh, three or four pounds of the dry sprouts can be used daily per cow. As a rule, they should be soaked in water for several hours before feeding, in order that they may swell up to something near normal size. Where one has a moist feed, like silage, he can mix the sprouts directly with it, and they will absorb moisture from the wet material. One would naturally give a feed rich in carbohydrates, like corn or barley, with the sprouts. A good mixture would be three pounds of malt sprouts, dry weight, two pounds of bran and five pounds of corn meal, with sufficient roughness to make up a liberal allowance.

The manure resulting from feeding malt sprouts is very rich in both potash and phosphoric acid and should be carefully saved for the purpose of improving the soil of the fields. Often one can buy malt sprouts at a cost not exceeding their manurial value. By studying combinations he can induce his cows to eat them in a reasonable quantity, and as the experience of many dairymen show, with good returns for the expenditure.



W. A. HENRY.

Wisconsin Agricultural Expt. Station.

For the Cow's Comfort.

ED. HOARD'S DAIRYMAN:—Having noticed the same disposition in my cows as D. H. Otis calls attention to in DAIRYMAN of May 19th, page 271, I have planned for an open shed on a knoll near the barn, and watering place. I shall keep this shed well littered with straw or other waste material. for the porpose of saving manure. There will no small amount of fertility accumulate there during the pasture season. If not cared for it will be almost a total loss. L. A. P.

Gentlemen

The Gluten Feed finally got here; It arrived here the 16th, was glad to get it for our cows were failing in their milk every day. They have gained in the last four days to twenty five gallons more per day than they were while we was out of the Gluten Feed.

We think Gluten Feed is second to none as a milk producing feed, it makes more milk and better milk than any other feed we can get.

Yours Respectfully
John Shugart & Son.

Cedar Hill Jersey Farm Notes.

Rape for Cows—Peas and Corn—Pastures.

ED. HOARD'S DAIRYMAN:—While we have been building the necessary rooms etc., at Cedar Hill farm, our farming operations have not been neglected. We have 25 acres of corn that is just coming up, and was worked over yesterday by our farm manager, with a Hallock weeder. This tool is a new thing with us, but is proving a good thing.

We have a 24 acre field of clover that we are letting stand because we have more plow land now than we can work properly. The stand is a very poor one; if we cut one ton per acre we will do well. This field was dressed with rich manure this spring, but we will have to wait for some other crop to pay us for the work of spreading. Speaking of manure, we have solved the question of how to easily spread it; we use a spreader, which saves a good deal of hard labor, and makes the manure go a great deal farther. Our boys make no kick now when they have manure to move.

Rape for cows! Who among the DAIRYMAN readers have tried it? We have sown several acres as an experiment. Let us hear from those who have used it in their dairy herds.

Peas? Yes, we have sown three acres of them, and then we took our corn planter (2-horse) and planted over the ground sweet corn, by planting two rows, then straddling one of the rows and again planting, making rows about 18 inches apart. As soon as corn and peas are up we will cultivate with our weeder a few times. This crop is for soiling.

Besides this crop we have four acres of sweet corn alone. Stowell's Evergreen is the variety used. This is one case where our father's way of dairying was a valuable lesson to us. No soiling crop has given us the satisfaction that sweet corn has, and the variety named above has always been our choice, as well as our father's before us.

Pastures? O my! After four years in the southern states where tame grasses were almost unknown, we are in a position to fully appreciate the great value of blue grass; our pastures today are waving like ripening grain in the wind, they are so high.

We have self fastening stanchions, but fully one-half of the cows are too full and lazy to spring them by reaching for the feed in their boxes. Our calf crop now numbers 17 head of heifers, all born since March 1st; they are doing nicely, are not allowed green grass while getting milk; they get bright clover hay in its stead. They do better on such feed. BUFF JERSEY.

Butter—Washing, Salting and Packing.

ED. HOARD'S DAIRYMAN:—I notice quite a little discussion of late upon the subject of churning butter to its granular stage—washing, salting and packing the butter at once, without working the butter, or at least reworking it before packing.

The complaint seems to be that it leaves too much brine in the butter. It can be done provided everything is all right, and proper rules followed, but there are many little things pertaining thereto that cause different results from what is anticipated.

Different skimmings of cream when not thoroughly stirred when different creams are added, or the cream is too sour, and quite possibly the new pupil *knows* the finger test is more reliable than the thermometer—if too warm the butter comes soft, runs together, and the granules are not granules.

If the cream is too cold it takes too long to churn it, if too sour it comes in a sort of mushy state and the buttermilk does not separate from the butter, and insists on running out with the buttermilk. Salt and water added with a few revolutions of the churn, will cause the butter to disunite from the buttermilk and float on top.

Salting granular butter in the churn is an entire different process from salting in many other different ways. There is ignorance on the part of many as to salting butter, particularly so, as to salting butter in this manner in the churn, and also as to the so called "brine salting".

It seems to be supposed that putting unsalted butter into a bath of strong brine and letting it remain there a few hours, that the butter will absorb the salt flavor and thereby become salted. This is a great mistake; butter does not absorb salt in the least, in coming in contact with the salted water or brine; it is only salted in proportion as the brine becomes a part of the butter, and that brine so entering the butter and remaining in it as a part of the butter, unites with the water in the butter and the butter is salted just in proportion as the brine becomes diluted with the water already in the butter.

I think it is safe to say that no one who has undertaken to brine-salt butter, has continued the process for the reason that they failed to get the butter salt enough. The fact is, butter does not take salt; it remains in the butter only as brine or undissolved salt. Make fresh butter into balls and immerse them in brine as strong as it can be made, for six months, cut them open and you will find them still fresh.

In trying out lard the heat evaporates the water—put in salt, and on the cooling of the lard, you will find the undissolved salt.

Many insist on taking out the butter, weighing it and adding one ounce of salt to a pound of butter, without a thought of how much water there is in the butter, and assume that as they have been exact, the butter will be salted the same every time. If butter is placed upon the worker, the main part of the water contained in it is soon removed and then the salt sifted on while more working is done; the salt so added mainly remains in the butter. But this is not our case.

We are proposing to churn the cream to granulation, wash it, and let it drain; then we claim that if it has been done right the granules will permit the added salt to mix more evenly through the butter and the moisture in the butter will very soon dissolve off the acute angles of the salt in the butter so as to soon destroy the scouring character of the salt on the grain of the butter, hence we see the desirability of having a salt that will dissolve quick.

After adding the salt and revolving the churn a few times it will be well to allow a little time for the salt to dissolve; then, the churn should be revolved until the butter works into balls, when it will be found that more or less brine has separated from the butter, which can be drawn off.

Assuming we have 15 to 20 pounds of butter at one time, this brine to draw off, maybe a pint or even less, or it may be as much as four quarts. If we have about 15 pounds of butter, that amount of butter would be entitled to about one pint of water to hold the salt and if an ounce of salt had been put in the butter and a pint of brine had come out after salting, about half an ounce of salt to the pound would remain in the butter which would be about right. But if four quarts of brine had come out instead of one pint there would be very little salt left in the butter.

It seems to be conceded that butter is entitled to have twelve per cent of water to remain in it—that this water holds the salt—that salt must not show in the butter undissolved.

I claim that there is no better way to add salt to butter than in the granular state in the churn, but there is no certain means of knowing how much water is left in the butter after all the water has drained out, so that not a drip remains.

If the cream has been churned rather cold the granules will remain quite fine and more water will remain in that will not drain out; or, if churned a little warmer or until the granules are coarser, much less water will remain in the butter after drainage.

If 20 pounds of butter are in the churn in fine granules, the salt added, the churn revolved to mix well—then the churn to rest awhile for the salt to dissolve—then the revolving of the churn continued until the butter has formed into balls, there will be found some four quarts of brine to come out.

On the other hand, if the churning had been continued until the granules were coarse, probably the surplus brine would not have been over one quart or even less. It must be plainly seen that all the water that was in the butter is all salted alike, that which comes out, the same as that which remains in to hold the salt, and if one quart remained in the butter to represent the twelve per cent, and one quart came out, half the salt has come out, that if four quarts came out, three-fourths of the salt has come out, hence the necessity of adding more salt.

It seems to me that the claim of brine salting is untenable, for the twelve per cent of water to remain in the butter can hardly be made salt enough to flavor the butter. If so, why dilute the strength of the salt by adding water to it, before applying it to the butter, when we already have too much water in the butter.

Prof. Farrington gives us valuable information relative to the action of salt on butter, claiming that salt aids in taking the surplus water out of butter. This is clearly correct. For instance, pack a barrel of pork using say fifteen pounds of salt—there is apparently no water visible—if weighted, in a few days we find it covered with brine, without the addition of water; no doubt this is caused by the action of the salt.

Rub a fresh ham with salt and much water soon exudes; salt a green hide, water exudes, runs off, and the hide I think weighs less than it did before salting, although the added salt has gone into the hide, and when made into leather, the leather will weigh more than it would have weighed, had no salt been used.

I do not believe that salt has much of any effect on preserving butter other than aiding to get out the surplus water; that "butter to keep" must be as free from the leaven of decay as possible, or what Prof. Russell denominates bacteria.

All the evidence I can bring to bear on this subject from a long and close study confirms the correctness of Prof. Farrington's late article in the DAIRYMAN.

As to the question of packing butter direct from the churn without working other than that done by packing—yes, it can be done without leaving two quarts of extra brine, provided it is done right, which is mainly to observe the correct temperature, and give the salt a little time to dissolve, and produce its effect on the surplus water in the butter, and solid work is done in packing.

However, I think the novice will do well to pack the butter and let it stand twelve hours, more or less. Then repack in another tub, when the operator may find that two quarts of brine may come out in the operation.

A good lesson in this line is to pack a tub from the churn without working—let it stand in a cool place a few days, then loosen the top hoops, turn the butter out on the cover, and you will quite likely be surprised at your imperfect work in packing. You will no doubt find ragged holes all around, to give ample space to hold that two quarts of brine. F. C. CURTIS.

Some Ideas about Cows.

A General-Purpose Sample.

ED. HOARD'S DAIRYMAN:—While I do not believe in a general-purpose animal of any kind, the repeated arguments wear on one until he unconsciously takes some "stock" in them, and when I found a large cow that "looked" right, I began to investigate.

I was attending an institute in New York and her owner invited me to supper and to see a cow "as was a cow". One-half Holstein, one-quarter Durham, and one-quarter native—milk, beef, hardiness and appetite all in one. Weight 1,200 pounds, color mixed gray and black, dairy type and beef form, milk record 50 pounds per day, 50 pounds butter in 28 days, milk testing when fresh 4½%. One calf sold for $48 at 18 months, for beef; another sold for $35 at 9 months, for breeding. She had been bred to a prize winning Short-horn. What more could one ask or expect?

I bought her and Friday afternoon started to lead her home. This paragon was gentle and could be led with a tow string.

Arriving at the ferry, the wind blew so I could not cross, and an old man invited me to go and see "some good stock." I would rather had him "enthuse" over *my cow*, but it was of no use. At his barn I found four head of full blood Short-horns, three steers and a four-year-old cow. The corn stalks were four feet deep in the yard. The steers were fat as mud, and the cow not much less. She would apparently give three quarts of milk at a milking.

"What good are they?" "The cow raises the calves, and at 2 years I sell them for beef."

"But beef does not pay, will not sell for enough to pay for the feed. Butchers will not pay a cent more than the price of western beef at the store house" I urged. "Yes it does! I make double, keep the feed on the farm, and only have the labor of feeding".

I got out my pencil and paper and after considerable urging got him to state how much grain he fed per day, and weight of hay and stalks, for one side, and the weight and price of beef for the other. When it was all figured out, the balance showed he was losing his labor and $5.00 on each animal, providing the cow gave milk enough to pay her keep.

He was as much astonished at the result as I was, and was as mad as a hornet in a minute. You see he liked to be noted as producing the finest cattle in the town, and it *hurt his pride*, to find it cost more than it come to. He was well off and had not been obliged to figure cost.

You "fellers" that figure are fools, was his parting shot, as I gracefully(?) withdrew. I thought more of my cow than ever.

On my way home, I arrived at friend Ferris' farm and was invited to rest my weary legs and "elephant". "Where *did* you get that?" he inquired. He keeps registered Jerseys and they did look small to me. I was tired and his question did not sound so funny as it would sometimes, when one was in a different mood, and I proceeded to explain, but it was no use. I have noticed that about Jersey breeders before. In vain I told him she would give more milk than two of his, raise a bigger veal, feed more pigs and bring more for beef when played out.

He replied, "I do not want to lug two pails of milk to get a fair yield of butter; do not want to raise a calf which will not sell for over $8.00 at 4 months, and could not afford

Jersey Bull Calf for Sale

Eight months old. Solid color. Perfect dairy form. Sire, Ida's Rioter of St. Lambert Jr. A 75 per cent son of old Ida's Rioter, out of a granddaughter of Matilda 4th. Dam of Stoke Pogis stock. She has given 38 pounds of milk per day testing 6 per cent Babcock. $30.00 gets this calf crated, registered, f. o. b. Adrian Nearly ready for service. **J. W. HELME, Adrain, Mich.**

FOR SALE Improved Farms near churches, schools, good market, healthy climate, rich prairie land, sure crops, good buildings, good water, and good neighbors. For particulars write to F. C GREENE, Real Estate, and Justice of the Peace, Renville, Minnesota.

HOMES FOR THE HOMELESS.

Texas Texas Texas

The cheapest homes, the lowest taxes, the best free schools, the finest farming land, and best cattle, sheep, hog and horse country in the United States. **Twenty Million Acres** of public free school land on the market at $1.00 per acre on 40 years' time.

Now or Never! Now or Never!

Send $1.00 at once to the undersigned for a copy of his new book stating all about these lands and how to buy them. It will be worth $1000 to you. If you have not the money now, cut this ad out and send for book later. **CHAS, P. SCRIVENER,** Special School Land Agent, Late State Compiling Draughtsman, **Austin, Tex.**

BINDER TWINE BLUE LABEL BRAND

...MANILA...	STANDARD	.... SISAL ....
9 1/2c PER POUND	8 3/4c PER POUND	8 3/4c PER POUND

Above prices are for twine on cars at Chicago or St. Paul. If shipped from Omaha, ¼c per pound higher. We have complete stocks in Chicago, Omaha and St. Paul, and can make shipment twenty-four hours after we receive the order. All orders must be sent to us at Chicago. Prices quoted are net cash with order. No discount allowed. Put up in sixty-pound sacks, which we cannot break. We guarantee these prices until June 25; after that you may have to pay more, so do not delay ordering. MONTGOMERY WARD & CO., Chicago.

to feed double the grain, which the big cow requires for the skim milk. My cows make more butter than she will, of better quality and it will sell for more. My dairy averaged over 300 pounds of butter per cow, none was sold for less than 20 cents per pound, and I fed but little except ensilage and bran."

His arguments were heated with facts, but I smiled at his "bigoted notions" after I had gone on a ways.

In course of time she dropped a big, raw boned bull calf, which required nearly a pail full of milk to keep him from bawling for more. He did not grow a pound faster per day, than our grade Jerseys, which required only a few quarts. I was glad to let another "one like me" fellow have him, as the price of veal is not "extravagant" now

The cow gave a nice mess, but on the Jersey amount of food, did not seem to gain. Her ration was increased, and she proved better.

The butter was white, or rather light colored, and required coloring. When the warm spell came, the butter melted in the jar and nearly required a spoon. Wife remarked, with emphasis, "I hate such butter. What ails it? We cannot send this to our customers. Say, your new cow is making this trouble."

I felt down in the mouth, and to encourage myself, went out to the pasture to look at her. She was a handsome cow. That big udder (for the scoopshovel full of grain, and the grass had done the work) was cheering, and I felt better.

Our pastures are flat and soft. As I drove her toward the barn, I noticed her big foot cut a hole in the sod, which did not argue well for future feed.

Her big udder swung back and forth, weight enough to break a back, and mopped up mud from her legs and the ground, when she sunk in too much.

She waddled through as graceful as a traction engine in the mud, and I washed her pretty much all over before I could milk. My wrists ached when I had drawn 25 pounds of milk, but I took pleasure in the big mess, for a few minutes, till I remembered the style of the butter.

The more I studied the subject, the less I believed in general-purpose cows, and I finally came to the conclusion she was intended for a dairyman who was selling milk by the hundred. The man who was feeding for beef would not have her; the butter man would not have her; the woman with private customers would not have her; I would not dig her out and wash her; so the milk shipper got her. She belongs in that tribe.

Moral. Study your surroundings. Buy the cow bred for your business.

Peruville, N. Y. C. E. CHAPMAN.

Skim Milk Calves.

[Press Bulletin.]

Allow the calf with the fresh cow four or five days. This gives the calf a vigorous start and aids in reducing any inflammation in the udder of the cow. Wean by feeding 10 pounds (1 quart equals about 2 pounds) whole milk daily in three feeds, and gradually increase the amount to 12 or 14 pounds, always weighing or measuring each feed. More calves are lost by overfeeding than for any other reason. When two weeks old the calf may be changed to skim milk, but not faster than a pound a day, i. e., the first day give 11 pounds of whole milk and 1 pound of skim milk, the second day 10 pounds whole milk, 2 pounds skim milk, and so on until the change is complete. The amount of skim milk may be increased gradually, but not to exceed 18 to 20 pounds daily per head. Flax seed gruel may be added to replace the butter fat. This is made by mixing ground flaxseed in cold water, adding boiling water and allowing to steam a few hours with cover on the pail. A teaspoonful of this gruel is enough at first, but this may be increased gradually to one-half pound of the meal daily per head. Flax seed is better than linseed meal since the oil is needed to replace the butter fat. Blachford's meal is an excellent calf feed and may be used the same as flax seed. The College recently started an experiment with calves, feeding part on fresh skim milk from the hand separator and part on sterilized creamery skim milk, and at the same time is testing the value of flax seed meal and Blachford's meal for calves, against skim milk alone. All the calves are allowed what kafir corn meal, hay and green alfalfa they will eat. The results are being watched with great interest.

Calf milk must always be fed blood warm, 95 to 100 degrees F., and a careful feeder will occasionally test the temperature with a thermometer. Skim milk not used when separated may be cooled and rewarmed when fed. Sterilizing creamery skim milk greatly increases its value for calves by enabling the farmer to keep it sweet until the following morning. At the College we keep sterilized creamery skim milk sweet from Saturday until Monday morning by cooling to between 56 and 60 degrees F., the temperature of well water. Sweet milk at one meal and sour at the next, causes scours, and seriously checks the growth of the calf. Sterilizing skim milk has an additional advantage in that the heating helps to prevent scours.

Calves will begin to eat meal when ten days to two weeks old. Put a little in their mouths after feeding the milk, and they will soon eat from the feed boxes with a relish. Never mix the grain with the milk. We find kafir corn meal an excellent grain for calves. It is constipating and checks the tendency to scours. Our calves that average eight weeks of age consume two pounds daily per head. As the calves grow older and eat more grain the kafir corn may be mixed with oats, bran or oil meal.

Calves will nibble at hay about the time they begin to eat grain. Mixed or prairie hay is good; alfalfa or clover is better. Our calves have been eating about one pound daily per head of mixed hay. Before turning on pasture in the spring it is well to feed some green feed which may be increased gradually until calves get all they will eat. A sudden change to pasture is apt to produce scours.

Calves can be prevented from sucking each other's ears and mouths by leaving them tied separately for a half hour after feeding. Calf buckets may be kept clean by rinsing and scalding after using. Calves need clean fresh water and salt.

To summarize, warm, sweet milk, fed in clean buckets, supplemented with a little ground flax seed or Blachford's meal, with access to corn or kafir corn meal, bright hay, fresh, clean water, salt, plenty of sunlight, shelter and bedding in cold weather, shade in summer, and regularity and kindness in treatment will usually insure good thrifty calves that will gain from 1½ to 2 pounds daily.—Kansas Experiment Station.

Put Money In Their Pockets.

ED. HOARD'S DAIRYMAN:—We like your paper very much. We got some ideas on feeding rations this last spring which put money in our pockets for which please accept our thanks. KNAPP & PIERCE.

East Claridon, Ohio.

How true is it, as the old proverb runs, "That unto him that seeketh light shall light come." It is the men who want knowledge, that find knowledge.

CONCERNING OUR ADVERTISERS.

BALL BEARINGS ON THE FARM.

It is probably a safe prediction that all manufacturers of harvesting machinery will eventually adopt ball bearings wherever it is possible to use them. In 1891 the Deering Harvester Company, of Chicago, equipped all their machines with ball and roller bearings, and the great popularity of the idea led other manufacturers to experiment with several styles of roller bearings, hoping to apply them to their machines without appearing to imitate the originators too closely. The application of ball bearings is more costly, but popular demand will yet force all competitors to follow the lead of the Deering Company.

The attention of our readers is called to the advertisement of Mr. Chas. P. Scrivener of Austin, Texas, Special School Land Agent, which is certain to interest everyone who is without a home, and who wishes to secure one in a mild climate where every branch of agriculture and stock raising can be engaged in. Texas is attracting wide attention, and the fact that her legislature now in session has just passed an act in accordance with the decision of the Supreme Court of Texas, placing the entire Public Domain of that great state on the market at $1.00 per acre on 40 years' time at 3 per cent interest, is certainly an excellent opportunity for the securing of cheap homes. Mr. Scrivener's book will give you full information in regard to the resources of Texas, and the character of land in the various sections of the state, and will also contain full text of the law regulating the sales of school land, together with a copy of the present act of Legislature and a map of Texas by counties.

VETERINARY.

Queries in this department answered by WM. HORNE, M. D. V. S., Janesville, Wis.

COW PHYSIC—Three-fourths to 1¾ pounds Epsom Salts (according to age and size of animals) and two ounces of best ground ginger. Pour over this three pints of boiling water. When at 105° F., give gradually as one dose.

IUJURY FROM BITE.

My colt was bitten last year about May 1st, it took me about three months to heal it up, stayed well until this April when it broke out some just as before, runs a yellow matter all around leg from hoof up to first joint but swells up to hock joint. She fattens very fast when this heals, and falls away very fast when it breaks and runs. She is two years old. J. K.

Enterprise, Miss.

ANSWER.

You don't say how or by what the colt was bitten. Chloride of lime 2 drams, oak bark tea, strong, 8 ounces, mix and sponge the leg affected 12 to 20 times a day for 2 days only. Don't use any more of the chloride of lime solution, but instead, keep wet with the strong oak bark tea 1 quart, acetic acid 4 ounces. Soak a 12 foot, strong, unbleached cotton bandage and wrap around the swelled leg evenly. Let it overlap just one-half over the other. If it causes much pain, remove every once in a while and replace, keep it wet with the solution. Give good exercise daily.

CLOSED TEATS.

We have a two-year-old heifer that has come in and both of her front teats are entirely closed, no milk runs out of the quarter into the teats. Also one hind teat that the milk comes out of the quarter into the teat very slowly. Would she be liable to be all right at the next calving.

We have two more that have trouble with their udders One has two quarters that let the milk down very slowly, and the other has a teat with an obstruction about midway. Can get milk with a tube, but it gets inflamed sometimes. K. & P.

East Claridon, Ohio.

ANSWER.

First. I don't know of anything to be likely to help this case but some form of bistoury. See ads. in the DAIRYMAN. I think she may come all right as the next calving.

Second. Can't say just what to do; but milk patiently and gently, using gentle, long continued massage, daily.

Third. You need an easy milk tube. You need a dilating plug to permanently dilate the channel of the teat.

BULL WITH COUGH.

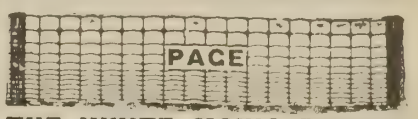
I have a bull that has been troubled with a cough, for the last eighteen months. About thirteen months ago a lump gathered in his throat and broke; it contained about a pint of matter. The sore healed at once and never bothered him again. Could it be tuberculosis? The bull is fat; no discharge of any kind. C. R.

Spanaway, Wash.

ANSWER.

No, it is not tuberculosis. Find the exact spot where the lump formed, then cut off the hair close, and then apply Gombaults Caustic Balsam; rub in the first application, then apply with a thumb sized paint brush, until you have a good sure blister, then cover daily with hog's lard until all the scabs are off, then repeat the treatment. Do all this in a thorough, systematic way and you will be likely to make a permanent cure.

SWELLING IN UDDER.



Have a Jersey cow with right side of udder swelled and caked hard. Gives bloody milk from right fore teat when first beginning to milk, also some lumps at first. Limps on right foot and appears sore in that section of udder. Have been rubbing udder with liniment and put bran poultices on udder, but does no good. D. M. B.

Bonham, Texas.

ANSWER.

Immediately full dose of physic and repeat once or twice. This is your chief reliance for a cure. Each morning give two, only, teaspoonfulls of nitre for ten to twenty days. Rub the swelled udder with strong camphorated spirits six parts, common turpentine two, only, parts. Rub hard the first time and repeat in the evening. Rub once a day after this for three to five days, until not needed. The physic is your surety for recovery.

WHO IS TO BLAME. Women as well as men are made miserable by kidney and bladder trouble. Dr. Kilmer's Swamp-Root the great kidney remedy promptly cures. At druggists in fifty cent and dollar sizes. You may have a sample bottle by mail free, also pamphlet telling all about it and its wonderful cures.

Butter—Churning and Working.

ED. HOARD'S DAIRYMAN:—In your valuable issue of May 12th, W. C. Rockwood gives E. J. T. good advice about working butter in churn, a method which I have followed for years. I like to churn at as low a temperature as possible—to get butter in thirty to forty minutes—and wash in water at about 50°. If the room was very cold, this might be too low.

I have discarded the use of the fork entirely. Turn churn from side to side to expose fresh granules, when sifting on salt, till it is all added, put on cover and revolve twice very slowly, and let it stand five or ten minutes. After revolving churn a few times draw off what little brine there is, for when the granules are small and firm they will not unite without an undue amount of working, if there is much brine in the churn. Draw off brine three or four times. In three competitive tests my butter has scored perfect in grain, salt, color and package. Am sorry I can't say the same regarding flavor. I never use any coloring, for my cows are pure bred Guernseys. A. H. KELLOGG.

Washington.

Grade Jersey Records.

ED. HOARD'S DAIRYMAN:—I enclose a clipping from the *Waupaca Post*. It is just what I am doing and have done through the aid of your paper and hope to do better still in the future, as I am just getting fairly started on the road to success. My cows are all grades with ages from 2 to 6 years old. I will just mention what they did in 90 days, from Jan. 1st, '99 to March 31st, '99.

From an average of 12 in number, we churned and sold 1,342.3 lbs. of butter, netting us at the creamery $216.81.

Waupaca Co., Wis. THEO. A. BAUER.

The champion cow in the herd of Chas. Bauer & Son, in seven months and ten days, produced 6,466 pounds of milk, 362.54 pounds of butter, which was received at the creamery and netted them the handsome sum of $60 35. Age 6 years.

Second best cow in one month and twelve days, gave 1,684 pounds of milk, 82 50 pounds of butter, netting $13 30. Age 5 years.

Third best cow gave in three months and ten days, 2,982 pounds milk, 168.43 pounds of butter, netting $27.22. Age 5 years.

Fourth best cow gave in three months and nineteen days, 3,024 pounds of milk, 165.46 pounds of butter, netting $27.10. Age 5 years.

Fifth best cow gave in three months and one day, 3,145 pounds of milk, 142 23 pounds of butter, netting $23.08. Age 4 years.

Sixth best cow gave in three months and seven days, 3,050 pounds of milk, 139.62 pounds of butter, netting $22.60. Age 4 years.

The milk is weighed twice a day at the barn and recorded. About the middle of each month samples are taken of two or more milkings, and tested by the Babcock test for butter fat, from each cow separately, and at the end of each month is figured by the amount of milk given by each cow, one-sixth being added for overrun. Cash is figured at Weyauwega creamery, prices ending March 31, 1899.

We wish to say to those who do not claim to know all about the management of cows and their product, to subscribe for and study HOARD'S DAIRYMAN, a weekly paper for the sum of one dollar a year. It is the best dairy paper in America, as it teaches how to weed, breed, feed, and handle dairy cows for profit, and if its teaching is put in practice, success must surely follow. B.

Concerning Food Adulterations.

The New York *Tribune* has espoused the cause of pure food reformation. It thinks that the evils of the army food controversy may carry with them some benefit to the people; says that the controversy has directed much needed attention to the quality of the food put on the general market, and that large quantities of canned and preserved goods are treated with injurious substances—expensive products being not infrequently stretched out with cheap adulterants. Filled cheese is an article that has discredited abroad the legitimate products of the American dairy, and, like oleo, is doubtless still imposed on Americans at home. Preparations are used to increase the natural yield of butter from milk, which really do nothing but produce curd to mix with the butter fat, thereby fraudulently adulterating it. In one of the leading trade journals of the meat-packing industries are several advertisements of chemicals for preserving meats. Of one liquid it is announced that "it cannot be detected." Another notice tells us that, "the preserving of meats demands modern methods" and offers to supply boracic acid to packers from New York, Chicago and San Francisco. There must be a demand for this modern method of preserving which gives business enough to a company to support three houses. In the same paper we are informed that "perfection in curing meats is attained by" a proprietary article whose name, the *Tribune* says, suggests embalming fluid. A study of agricultural journals will discover other chemical preparations made for use in fruit, vegetables and meats. Disguised creosote is offered to save ham smoking; salicylic acid under cover for canning corn and keeping cider. Hundreds of nostrums are on the market, and their owners seem to make a living out of them. It is evident that they are largely used, and the result is that innocent purchasers of food are imposed upon by goods secretly treated. The man who buys a ham painted with chemicals believing that it has been cured by smoke, is cheated, and so is the man who buys what he supposes is pure butter, but is really part curded caseine. Some time ago the Agricultural Department made an exhaustive examination of the canned fruit and vegetables found in our markets, and the result was a most disquieting report. Salicylic acid, lead, copper salts, sulphuric acid and other deleterious substances were found in the most expensive as well as the cheapest grades of goods. "Firms of high repute, both at home and abroad, used them, and it seemed impossible for a private consumer to secure pure canned goods with any certainty." Corn, peas, French beans, baked beans, pickles, and a dozen other things showed more of adulteration than of purity. Whenever attempts are made to take really effective measures to stop the adulteration, certain canners object. First they say they never use such things. Yet such things are found in their products. Then they proclaim the necessity of using some harmless antiseptic to preserve certain vegetables without destroying their flavor by over cooking. Nevertheless no manufacturer would admit that any particular goods of his were so preserved. If he did he would not sell them. The Department of Agriculture says: "Dosing of food with cheap antiseptics sav s time and trouble, and enables the canner to be quite certain of the keeping qualities of his goods, no matter in how slovenly or sloppy a manner his work may have been conducted. For this reason antiseptics are daily growing in favor among the preservers."

The *Tribune* prints some facts concerning the Pure Food laws of New York, and the difficulties in guarding against adulteration are pointed out. One of the most serious is the argument against injuring industry, the same that was some time ago brought up against going to the bottom of the army beef charges and proving or disproving them. It is urged that too strict regulations in New York would injure local canners at the expense of Westerners; that any exposure of their adulterations would discredit local goods in the West and American goods in general abroad. Of course, the answer is that dishonest canners have no right to such consideration. If their chemicals are harmless, let them use them openly. If they do not use them, they are all right, and need not fear laws which they do not break. The Brosius Pure Food and Drug Bill will not be passed by the present Congress. It should not be unless honest tradesmen, whether engaged in the wholesale or retail business, should be safe-guarded, as *The New Jersey Trade Review* has pointed out. Indeed, one of the most prominent promoters of the Pure Food and Drug Congress remarked to us the other day: "The amendments suggested by you are essential; and, before the Bill is passed, its promoters must accept them."—*The New Jersey Trade Review*.

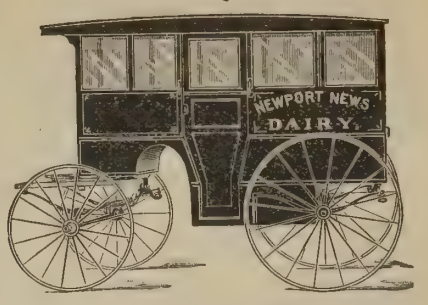
Peterboro, N. H.

No ingenuity of barbarism—no devilish invention of the masters of torture during the time of the Spanish inquisition ever devised an agony so intense, so persistent, so long enduring, so nerve-harrowing as that which is suffered day after day by the women whose distinctly feminine organism is deranged or diseased. There are three most trying times in every woman's life; 1st—when girlhood blossoms into womanhood; 2d—when motherhood is achieved; 3d—when the capacity for motherhood ceases (the change of life.)



Dr. Pierce's Favorite Prescription was devised to make these three periods safe and painless by restoring to vigorous health the organs involved. It soothes, heals, nourishes. It gives Nature just the help it needs. It is the only preparation of its kind devised by a regularly graduated physician and skilled specialist in the diseases of women.

Me-too-medicines are preparations without standing or success. They are the substitutes sold as "just as good." Having no record of their own, when Dr. Pierce's cures are referred to they cry me-too, me-too, like the cuckoo in a Swiss clock. Don't accept me-too medicines for "Favorite Prescription."

Mrs. M. Barnes, of Balls Ferry, Shasta Co., Cal., writes: "My physician said I was suffering from the effects of 'change of life.' I had heart disease, and female trouble and rheumatism. My head was so dizzy I could hardly stand up. When I began Dr. Pierce's medicines I improved right along. I took seven or eight bottles of the 'Favorite Prescription,' a teaspoonful three times a day, and the 'Pleasant Pellets' at night. I feel as well as I ever did. I take great pleasure in recommendiug Dr. Pierce's medicines to suffering women. I think that they are the best medicines in the world."

The World Cannot Show Its Equal

In STYLE, CONVENIENCE and DURABILITY.

A Perfect Milk Wagon

On a Perfect . . .
Short Turning Gear

WE make the only drop center wagon that has a self-balancing, short turning gear. All parts are wrought iron forgings. It is so plain and simple that it can't get out of order and if any part should break, any country blacksmith can easily repair it. All other wagons of this kind have complicated gears, and mostly made of cast iron.

Write us for our Catalogue, which fully illustrates and describes this wagon and 10 other styles.

THE NEW BOOK
Feeds and Feeding

By Prof. W. A. HENRY.
Wisconsin Experiment Station.

This book should be in the hands of every stock feeder in the country. Every reader of Hoard's Dairyman ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

or

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehensive from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

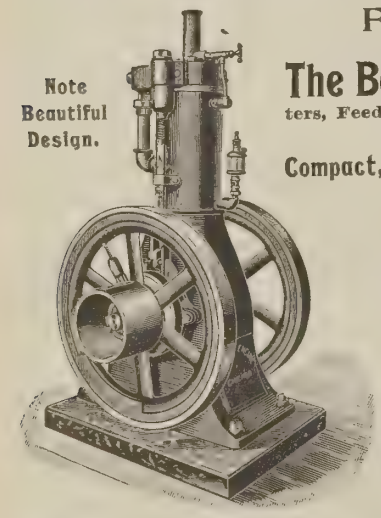
This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be refered to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price $2.

Lest you forget,

we say it yet:

SMALLEY CUTTERS



are much the best for

SILO WORK.

SMALLEY MFG. CO., Sole Makers, Manitowoc, Wis.

The Burrell Upright Engine

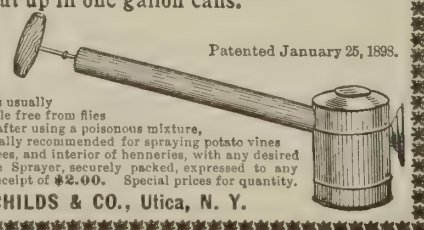
KILFLY.

More Milk, More Money, More Comfort for Cows and Milkmen.

A Liquid Mixture of Untold Value.
Applied with Childs' Electric Sprayer.



Protects cows from the torture of flies, thereby increasing the amount of milk. Absolutely harmless to man or beast. Put up in one gallon cans.

Once Tried, Always Used.

ELECTRIC SPRAYER

Patented January 25, 1898.

Convenient and Practical in Every Particular.

Throws a very fine spray of any of the liquids and mixtures usually used for destroying insects, bugs, etc., and for keeping cattle free from flies during the summer weather. Can be thoroughly cleaned after using a poisonous mixture, which is conveniently done by removing the cover. Especially recommended for spraying potato vines with Paris green, also all kinds of plants, bushes, vines, trees, and interior of henneries, with any desired formula. Sample Lot—One gallon can **KILFLY** and one Sprayer, securely packed, expressed to any address (except in State of Maine) charges prepaid, upon receipt of **$2.00.** Special prices for quantity.

Agents Wanted Everywhere. **CHAS. H. CHILDS & CO., Utica, N. Y.**

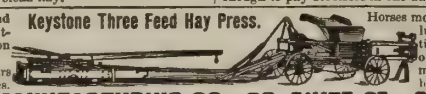
KEYSTONE QUICK HAYING MACHINES.

Keystone Side-Delivery Rake *means "Quick Haying, Quality Prime."* Turns the hay completely and leaves it in a light, loose windrow ready for loader. Its use means **air cured,** not sun bleached hay. **Better than a Sulky Rake and saves use of tedder.**

Rakes wide, fast and clean

Takes up no trash, that means clean hay.

Keystone Hay Loader.

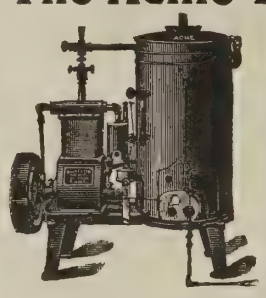


Loads the hay from the windrow or cock, or direct from the ground if the hay is heavy. Takes the hay up clean but takes up no manure, rubbish, &c. **It makes haying quick and easy.** In showery weather it often saves enough to pay for itself in one day. Loads a wagon in 5 minutes.

Made entirely of steel and iron. Horse power only. Mounted on steel wheels, and stands on the wheels when operating.

Write for our special circulars fully describing these machines.

Keystone Three Feed Hay Press.



Horses move in a full circle. Each revolution moves the plunger three times—**one more feed than any other press made.** Requires no more men but increases capacity beyond comparison.

A Wide Open Proposition.

We say for the **Sharples TUBULAR Cream Separators,** that they are remarkably close, rapid and effective skimmers, and we believe they are the most desirable separators for any large capacity creamery to have in use, If you wish to try one, we wish to have you do so, for these separators win on their merits. We will gladly ship you a machine if you will just write us as follows:

> Please ship to me a Sharples TUBULAR Separator. I will immediately put it into my factory and give it a fair and careful trial. If I like it in every respect, and it does all claimed for it, I will keep it and pay for it. If it fails to suit me for any reason I will notify you to that effect, and on receipt of instructions from you, will re-ship it to your order as you may direct.

We know 'tis a wide open proposition on our part and invites trouble from the unscrupulous creamerymen and unprincipled separator agents who swarm around every Tubular that is placed, trying by fair means or foul to displace it. But our faith in humanity is large. Out of hundreds of **TUBULARS** placed on such liberal terms, not a dozen creamerymen, disposed to listen to the unholy propositions of competitors, and take advantage of our liberality, have been found. A few betray our trust for reasons best known to themselves, but we try to steer clear of that kind.

THE SHARPLES TUBULAR SEPARATOR

The cream from it is superb.
The reserve capacity is large.
The clean skimming is unequalled.

The bowl is hollow.	It weighs 30 pounds.
It spins on air.	It skims 1 to 3 tons.
It is 4½ inches in diameter.	No rubber rings.
No metal bearings.	No spindles.

Little oil.

Send for Catalogue No. 46.

Subscriptions in United States and Canada $1.00 per year; 6 months 50 cents; 3 months 25 cents.

FOREIGN SUBSCRIPTIONS may be sent through Sampson Low, Marston & Co., St. Dunstan's House, Fetter Lane, London, Eng., or their agents, including the leading news dealers and book sellers in nearly all foreign countries.

All countries in the Postal Union $2.04 a year; not in the Postal Union $2.56.

Correspondents must not expect us to acknowledge the receipt of letters containing remittances for subscriptions. The receipt of the DAIRYMAN is sufficient notification that the money has been received. The label on the paper will show date to which subscription is paid. In case of renewals if date on label is not changed within two weeks after remittance is sent, inform us at once.

Remit by draft on Chicago or New York, or Post Office or Express Order; never by personal check.

ADVERTISING RATES.

Twenty-five cents per line, (agate measure) 14 lines per inch, each insertion.
Reading notices, 50 cents per line (nonpariel measure) each insertion.

PROFESSOR H. C. ECKLES, of the Iowa State Agricultural College, who is temporarily engaged by the Massachusetts Agricultural College to conduct the state dairy school at Amherst, has won eminent success in his work and new honors for the Iowa dairy school. At the recent state dairy convention held in Massachusetts, butter from the state school, of which Professor Eckles has charge, won the highest score.

A MICHIGAN dairyman who had been in the habit of buying fresh cows to replace those dried off, commenced to keep an account with each cow, and the first year he found that after charging each with her cost of food, and crediting her with what she produced, there was a wide difference in the cows. One cow gave a profit of only $9 per year, while another gave a profit of $41. Following out this policy he has changed the whole character of his herd, and today he finds that two cows pay him as well as three did previous to his experiment.

THE following table will illustrate the wonderful increase in the consumption of milk in ten years, in New York City, and presumably so all over the land:

Year.	*Cans.*	*Value.*
1888	6,062,216	$9,652,500
1889	6,630,278	11,675,500
1890	8 141,983	12,085,000
1891	8,269,953	14,128,677
1892	9,084,781	15,116,668
1893	9,303,315	16,249,354
1894	9,485,029	16,107,648
1895	9 336,827	16,778,823
1896	10,079,417	15,781,881
1897	10,338,356	15,872,841
1898	12,382,106	17,458,759

ASSORTED CURSES FOR THE DAIRYMAN.

With the coming of warm weather, the numerous troubles that affect the course of dairying take on a new and vigorous life. Warmth and moisture put new life into bacteria of all kinds, and particularly those that cause putrefaction. This class is numerous; they are of different shapes, sizes and conditions of growth, but they all unite in making trouble for the dairyman who permits them to be present in his neighborhood.

Not alone will they taint his butter and spoil his cheese, but they will kill his pigs, cause scours in his calves, obscure diseases among his other animals, and also deplete his pocket-book at a most astonishing rate.

Small in size but mighty in results are the whole race, and yet they are present only by sufferance of the dairyman and want of hot water, soap and elbow-grease.

The dairyman, or any other sufferer can reduce his losses from poor butter, poor cheese or dead animals, caused by surrounding dirt. Cleanliness is money to any man, soap will return a big interest, soda is his best friend. Combine these with drainage, whitewash and a vigorous and well handled scrubbing brush, and a dairyman can demand as others do, an extra price for his products, and, what is more, he will get it.

TYPES OF DANISH CATTLE.

A Cow of the Red Race.

RELATION OF DAIRY FARMING TO SOIL FERTILITY.

One of the strongest arguments for dairy farming, and one of its most important rewards, is what the farmer gets back in the maintenance of the fertility of his farm. Every well balanced farmer can see and appreciate this factor.

It is a grand thing to have a farm under you, that you can see and feel every year is a little stronger than the last. No intelligent dairyman goes along year after year, without considering how to keep up the productive power of his land.

He considers that the raising of good crops is a good deal more a matter of fertility, than it is a matter of season. He has taken notice in all these years he has lived, that a good, rich, quick soil raises a crop in all kinds of seasons.

Prof. Harry Snyder, of the Minnesota Experiment Station, has made some very interesting investigations, concerning the annual loss of nitrogen, potash and phosphoric acid on 160 acre farms, carried on under five different systems of farming.

SYSTEM OF FARMING	*Nitrogen.*	*Phosphoric acid.*	*Potash.*
	Lbs	Lbs.	Lbs.
1. Grain farming	5 600	2,500	4,200
2. Mixed grain and general farming	2,600	1,000	1,000
3. Mixed potato and general farming	2,300	1,000	2,400
4. Stock farming	900	* 50	60
5. Dairy farming	800	* 75	85

*Gain

Some idea of the money involved in these losses in fertility may be gained if we will stop for a moment to consider what it will cost us in cash to put back these elements of fertility, taken out. Taking the market rates on these three elements, which constitute the sum and soul of fertility we find that in grain farming there is annually lost, $84 worth of nitrogen, $12.50 worth of phosphoric acid; $21 worth of potash, or a total of $117 50.

In mixed grain and general farming there is an annual loss of $39 worth of nitrogen; $5 worth of phosphoric acid, $5 worth of potash, or a total of $49.

In mixed potato and general farming there is a loss of $34.50 of nitrogen; $5 worth of phosphoric acid; $12 worth of potash, or a total of $51.50.

In stock farming there is an annual loss of $13.50 worth of nitrogen; a gain of $2.50 worth of phosphoric acid; and a loss of $3 worth of potash, or a total loss of $14.50.

In dairy farming there was a loss of $12 worth of nitrogen; a gain of $3.75 worth of phosphoric acid; and a loss of $4 25 worth of potash, or a total annual loss in fertility of $11.

It should be remembered that in stock as well as dairy farming clover and other nitrogen producing plants, are grown as well as other nitrogenous products are bought.

But these figures will show how the drain in fertility is lessened by animal farming of both kinds.

TYPES OF DANISH CATTLE.

A Bull of the Red Race.

Silos, Separators and Feeding in South Dakota.

ED. HOARD'S DAIRYMAN:—Will you be so kind and answer the following questions:

1. Is a ground silo all right if walled up with cement? The ground is dry for thirty feet or more.

2. How large would it have to be for fourteen cows.

3. We haul milk to creamery about five miles, and feed skim milk to calves and pigs, but milk is often so bad, that it is not fit for use. Would it pay us to get a separator?

4. Is the Kneeland Omega Cream Separator, manufactured by the Kneeland Crystal Creamery Co., Lansing, Michigan, all right?

We have fourteen common cows which yield about 160 to 175 pounds milk per day at present. I wish to improve on them if I can. They were fed on little fodder, about four pounds corn meal and all the millet hay they want to eat. Most of them dropped calf last winter.

I am studying feeds for next winter. Can you help me out on that? Planted some sweet corn fodder, millo maze, and cane and millet for hay. A. H. MEYER.

Pukwana, S. D.

Silos built as suggested have given very excellent satisfaction in many places. Fourteen cows in Dakota would be abundantly served for the winter, by a silo fourteen feet in diameter and twenty feet deep, but we cannot advise going that deep in the ground. It has been done, and no accident as yet resulted, but there is a possibility of gas accumulating in the bottom of a silo that has no free outlet, that would be fatal to human life.

The writer of this reply has had a farm separator in his dairy several years, and sends the cream to the creamery. He is quite confident it pays, or otherwise would have discarded it. We have no personal knowledge of the separator referred to, but it has been favorably mentioned in several communications to the DAIRYMAN.

The cows were not properly fed last winter, as there was not enough protein in the feed, and protein is the one element without which milk cannot be made. You will need bran and oil meal, or gluten, or some other feed rich in protein, if you expect cows to give a good supply of milk, and return some profit for their keeping and care. These matters will continue to be discussed, from time to time in these columns, and a careful reading of the DAIRYMAN, from week to week, will show the proper proportions. Write us next fall, giving the prices of different feed stuffs, and a ration formula will be given.

Gathered Cream Creamery.

A Criticism.

ED. HOARD'S DAIRYMAN:—In your issue of May 26, page 297, Mr. A. Bartle, gives some very excellent figures showing the result of a well managed creamery. A few things need more extended explanation.

1. It is a very strange thing that the butter milk from 360,000 pounds butter sold for only $116.28. At 5 cents per 100 pounds it ought to bring $597.98, providing 23 pounds of butter are made from 100 pounds of cream.

TUBS.

The tub expense at $545.15 seems strange; 360,000 pounds, if all put in 60's, would require 6,000 tubs, which at, say, only 20 cents each, would be $1,200. Please explain.

HAULING.

One thing eminently illustrated in his report is the small sum for hauling cream from the farmer's door. 360,000 pounds of butter is equal to almost 9,000,000 pounds milk, which at, say, an average of 8 cents per 100 would cost the farmers $7,200, but it actually cost $2,964, according to his report. A very great saving indeed.

Jesup, Ia. J. N. NUNCEY.

THE fact that cream will not rise well on pasteurized milk has always been an objection to its use, and has probably prevented a wide spread adoption of the process for city milk. Mr. J. F. Woodward, a former student of the Wisconsin dairy school, working with Prof. E. H. Farrington, has found that heating the milk to 140° for thirty minutes, produces all the good effects of pasteurization at higher temperatures, and yet does not affect the creaming of the milk so treated. This discovery will be of material advantage to the city milk trade, and cause pasteurization to be more widely adopted.

THE *Jersey Bulletin* begins to see the light, and in a recent issue says it admits not only that the Babcock test is all right in creameries and cheese factories, but goes to the extreme of endorsing it as "all right" in testing milk at any time and place.

It is, perhaps, too much to expect that the *Bulletin* could say so much as this, and then leave the subject decently and in good order. We are, therefore, not much surprised to read further down the column that it does not favor the Babcock test *alone* in making or giving a cow a butter record. This is as much as to say that others do favor the test alone for such purpose, which is not true. Nobody pretends that the test makes butter, or does anything more than reveal the per cent of fat in the milk. But when we know this and know also the amount of milk, it is not very difficult to compute the amount of butter that can be made from that milk, when modern methods and appliances are used. When the churn and the test agree, each corroborating the other, we may be assured that both the testing and the churning and the subsequent working of the butter were skillfully and *honestly* done. Without a test of the milk or of the subsequent skim milk, and an analysis of the butter, no man can be certain that an undue amount of fat has not been left in the skim milk or that there is not more water left in the butter than is consistent with commercial integrity.

Why cannot the *Bulletin* be candid for once and tell the whole truth, by admitting that the churn alone is not sufficient for making or giving a cow an authentic butter record, and this more especially where the larger yields are reported.

It is not very material that the *Bulletin* misrepresents HOARD'S DAIRYMAN as it did some months ago by taking a few words from an article by a correspondent, of specific local application, and quoting them as an editorial expression of a condition universally existing; or as it did in the beginning of the article referred to above by saying that we lament that the "Jersey world is not a very large field anyhow." What we did say was that the *Jersey Bulletin's* field was not a very large one, which is a very different matter. Our subscription books attest the fact that the Jersey world is indeed a very large and important field, and our correspondence from Jersey breeders attests the further fact that HOARD'S DAIRYMAN is the Jersey cow's best friend

LOOK ON THIS OPERATOR, THEN ON THAT.

Every person of experience in creamery work knows that there are many very poor operators employed in creameries. They are wasteful and ruinous to the business. The reason why such men get a chance to run a creamery is because the patrons are looking for only one thing, a *cheap* man. Such men are very apt to impose themselves on co-operative creameries for the standard of judgment there is considerably lower as a rule than with proprietary creameries where the owner knows and feels that he must have good talent.

A writer in the *Chicago Produce* gives a bit of experience, which we have seen duplicated several times. He says:

There are men who are running creameries at a loss to their proprietors I have one in mind now, where the buttermaker was taking in about 6,000 pounds of milk a day and a station run in connection was taking in about 7,000 pounds daily, six days in the week, and was getting 9 tubs of butter, of 60 pounds each, a day. On Monday morning there was always more milk, as some of the patrons sent their Sunday morning's milk. The separator, which was an Alpha No. 1, had the pin out in the feed cup and was skimming something over 3,700 pounds of milk per hour. This man who had been in the factory for some time, did the Monday's skimming and Tuesday churned it. On Tuesday of that week I took charge of the separator and got it to skim at the rate of 2,500 pounds to the hour, after stopping two or three times to regulate the skim tube screw.

I had on Tuesday something like 400 pounds less of milk, but got 46½ pounds more of butter after it was packed than did the former buttermaker. Butter at this time was worth about 15 cents per pound; I would like to have what that man's loss to the factory was for my wages. This is not the only case of this kind, there are others; figure it up and see where your loss is. I believe I am justified in saying that three out of every five creameries that handle not less than 8,000 pounds of milk daily in the winter, either directly or through stations, are meeting with even a greater loss for various reasons, namely: the steam of the boilers is allowed to vary to such an extent that at times the separator is running at the rate of 7,600 to 8,000 revolutions to the minute, and again it runs down to 4,500 to 5,000; the milk is allowed to crowd the capacity of the machine, therefore not doing its work clean; it may be at too low a temperature when it passes the separator; all these things, with many others, will lose you two men's wages at least.

KANSAS DAIRY QUESTIONS.

When the Kansas Experiment Station started investigations at the Meriden creamery, it opened up a very large and interesting line of work. Records of results actually achieved, of the feeding, making and yield of the average creamery herd are of great value.

In furtherance of this work, a series of questions have been formulated and the intention is to have the skimming station men visit each patron of the creamery, and as far as possible find out by the aid of the following list, to what extent the patrons are following the line of modern methods of feeding and milk production. Following is the list of questions, together with a suggested form for keeping a record of a herd:

Month 1898.	*Milk from herd.*	*Test.*	*Lbs. butter fat.*	*Price of butter fat.*	*Cash receipts.*
January.....	2,064	3.9	80.5	17½c.	$14.08
.....	.....	.....	.....	.....	.....
December.....	1,547	3.8	58.7	22c.	$12.93
Total for year.	14,941	.....	547.8	.....	$99.96
Average per cow.	4.980	.....	182.6	...	33 32

1. Number of cows kept in 1898?
2. Number of calves raised in 1898. If sold, at what age and price?
3. Value of calves at weaning time?
4. Amount of skim milk fed to pigs?
5. Value of skim milk per 100 pounds for pig feed?
6. How do you feed skim milk to calves? (time of day and amount?)
7. What kind and how much grain do you feed calves on skim milk?
8. What kind and how much hay do you feed calves on skim milk?
9. What breed or breeds of cows did you have in 1898?
10. When were your cows fresh?
11. Kind of pasture?
12. How long were they kept on pasture?
13. Kind and amount of grain or roughness fed while on pasture?
14. Kind and amount of grain fed in winter?
15. Kind and amount of roughness fed in winter?
16. Water supply in summer?
17. Water supply in winter?
18. Do the cows get ice-water in winter?
19. Kind of shelter?
20. Breed of bull? Why?
21. Do you expect to increase dairy herd?
22. Can you keep milk sweet from Saturday night to Monday morning?
23. What dairy or farm paper do you take?
24. Problems confronting patrons?
25. General remarks?

PLAIN TALKS ON BACTERIA AS APPLIED TO FARM PROBLEMS.

[By Prof. H. L. Russell.]

Second Series, XVII.

FIRE OR PEAR BLIGHT.

Although this disease has been known for over a hundred years, its true cause was not discovered until the last decade. The wide devastation that it has caused in the orchards of the United States has brought it prominently before the attention of all fruit raisers, and much idle speculation based on crude and half developed hypotheses as to the cause of the trouble, has been spent to but little purpose. The two hypotheses of this class that have received the most support, ascribed the disease to the action of the pear tree-borer, or to the presence of frozen sap. These theories had no sound basis on which to rest, and of course led to no rational steps in regard to treatment. Gradually the idea began to be accepted that the disease was infectious, was communicable from tree to tree, but the cause of the infection was not determined until 1880, when Prof. T. J. Burrill, of the University of Illinois, succeeded in demonstrating that a specific bacterial form was the inciting cause. This discovery was of more than ordinary importance, as it marks the first plant disease to be worked out that is produced by organisms of this class.

The disease is ordinarily known as *pear blight*, because it attacks this species with great severity, but other related fruits are often affected, such as apples, crab-apples and quinces. Some of the wild species may also "take" the disease, if conditions are favorable. Wild hawthorne, service berry and wild crab are not infrequently affected. Last year the disease raged with unwonted severity in the north-central states, and many of the wild crabs of this region were found badly diseased. The disease is often called *fire blight*, because of the appearance of the leaves after the affection has broken out. The leaves themselves are not especially affected at first, but the disease establishes itself in the smaller branches, cutting off the supply of food and water from the tree. The result is that the leaves wither, turn black and give the appearance of having been burned with fire. The germ causing the trouble, finds in the inner bark, and in the growing zone just outside of the sap wood, the best place for its growth. Here it thrives luxuriantly, working its way down the tree, until it reaches a larger stem, thus cutting off the supply to a constantly increasing extent. The result is that all parts above point of infection are diseased. In severe cases, especially with pears, the blight may kill the entire tree; more often, however, the disease runs its course, and progresses very much more slowly, if at all, when it reaches the hard, firm wood of the previous year. In the apple the terminal twigs may suffer severely some years, and no evidence of any infection be observed the next year.

PLACE AND MODE OF INFECTION.

In order to forestall disease attacks, it is necessary to know where the disease germ is able to penetrate the host, and also the agent by which such introduction is accomplished. To fight an enemy in ambush is to fight at a great disadvantage, so before a rational notion as to the best method of combatting pear blight was formulated, it was necessary to work out these conditions. They are now fairly well known, and they illustrate in an exceedingly good way, the close inter-relation that exists between the different beings that inhabit our world.

If we examine a number of pear trees in the early stage of the blight, it is at once apparent that the two most sensitive points of attack are the blossoms and the young succulent twigs. In fact, succulence of tissues is a marked predisposing factor. These two phases often receive the distinctive titles, *blossom and twig blight*. They are however slightly different manifestations of the same trouble, and are produced by identically the same cause.

The germ, in finding its way into the blossom, is brought to this point by insects. Bees, flies, and other winged insects visit the flowers in search of nectar. This precious fluid is secreted in the naked, succulent tissue, known as the nectary; situated at the base of the flower. In loading up its store of honeyed sweets, it may dislodge from its mouth parts, germs of the pear blight, if it has come in contact in its visits, with any of the viscid secretions of this germ. If once the nectary becomes involved, the germ passes rapidly through the tender cell structure of the blossom into the flower stalk, and so on down into the branch or spur. When once inside of the dense outer bark, it is safe from ordinary harm, and in the delicate cells of the growing zone it finds a vantage ground.

The disease also starts in the terminal end of a branch, and from this point works its way back. Many such cases are due to the germ finding its way into the inner tissues by means of insect stings. The blossom blight is the most serious phase of the question, as the disease germ is widely distributed from tree to tree by insect visits. Not only may the whole orchard thus become badly affected, as to number of trees, but the blighted blossoms of course always fail to form any fruit.

A PRACTICAL DEMONSTRATION.

One can readily demonstrate for himself the presence of the blight bacterium in an affected tree, and show the influence of infection. From a pear tree that already shows signs of the blight, remove several of the affected twigs and cut them in pieces a few inches long. Stick them in a tumbler of water and note in the course of several days, the exposed cut end. Viscid drops of a whitish color will soon appear, that will later turn to a yellowish cast. This is the blight bacillus growing out of the cut end and living off of the food it can get from its host plant.

Now, if this diseased shoot is taken, and by means of a needle, some of this slimy

growth is pricked into a healthy, rapidly growing shoot, the infection will become evident in the course of a few days, thus proving the communicability of the disease germ.

CONDITIONS CONTROLLING INFECTION.

Some years the pear blight rages with unwonted severity, while the following years are practically free from the same. This, indeed, seems curious, with a disease produced by a germ cause, for it must be supposed that the germ is existent under certain conditions from year to year. Then why does it not appear with fair regularity? In germ diseases of all kinds, one of the main factors governing the spread of the disease, is the varying susceptibility of the host. There is no longer any question but that this factor also is strongly operative in the case of this disease. Some years the host plants that are normally susceptible (pear, apple, etc), become especially sensitive; even before the germ nature of the disease had been worked out, this had been noted. Springs with an excessive rainfall, especially if accompan'ed with a high temperature, are particularly favorable to blight. In all probability this is largely attributable to the fact that the growth of the plant tissue is much more rapid and therefore more succulent under these conditions.

Different varieties possess a varying power of resistance and Arthur has determined that this resistance was less in those varieties that had the least moisture in their woody structure. Succulent and rapid growth is often produced by good tillage or by over manuring, and it has been noted that blight is often much more severe in orchards that have been treated in a way so as to encourage rapid, luxuriant growth.

TREATMENT.

The treatment that might be recommended for this disease will be of two sorts: Methods that will increase the blight resisting properties of the tree, or will destroy the blight bacillus or prevent its spread. Cultural methods do have some effect on the spread of the blight, as has already been noted. Pruning, cultivation and irrigation all exert an effect on the tree, tending to favor the production of new wood, thereby giving better conditions for the spread of the blight. The use of highly nitrogenous fertilizers is also detrimental for the same reason. These cultural methods, while of some value, cannot exterminate the disease after it has once gained access.

Manifestly, any disease that is intrenched behind so resistant tissues as the bark, cannot be controlled by local application. It is possible, however, to check spead of disease by removal of affected organs. As these are invariably terminal structures (blossoms or twigs), this process can be carried out with ease, if it is done before too much of the new growth becomes affected. In many cases the disease "holds over" from year to year. Along the border of the affected tissue the blight microbe is able to persist for a long time. If not removed the disease may start up afresh the next season, if climatic conditions are at all favorable.

In cutting out dead wood, it is necessary to cut back beyond the wood that appears to be dead. The blight microbe is steadily forcing its way down the tree and is therefore always in advance of the diseased portion. All affected parts should be burned. To leave dead limbs in the orchard is to simply leave the disease germ where it may be widely disseminated. The old idea used to be that the germ wintered over in the ground, but the most careful experiments have failed to show such a condition to be true, although, of course, such may be true in spite of the negative results yet obtained.

Is Abortion Communicable.

Some Wisconsin Experience in the Negative.

ED. HOARD'S DAIRYMAN:—In the DAIRYMAN of May 19, page 281, I find an article on this subject, from Mr. P. M. Lewis, inquiring if the disease is conveyed by the bull, and the answer is: It is our decided opinion that the male can and does convey the abortion germ to the female, provided he has been in contact with an infected female.

Now, Mr. Editor, I would like to say a word or two on this subject, or rather relate some of my own experience which does not confirm this theory. I know your idea has been proclaimed at farm institutes, by one of the most successful, practical and experienced dairymen of Jefferson County, and by a number of other men, but facts are facts, and when they do not agree with theories, either the theories have to give way or the facts must be explained on some other basis.

In my case the facts are as follows: About 18 years ago I had a fine lot of cows and a first class Guernsey bull. Unfortunately for me, and from causes I could never explain or account for, abortion broke out in my herd with great fury. Not only did the cows lose their calves, but it was well nigh impossible to get them in calf again. They would come in heat regularly, and were served again and again without avail.

During this time one of my nearest neighbors brought all of his cows, eight or nine in number, to this same bull for service; another brought six cows 2½ miles, a third seven cows 3 miles, and several others one and two cows. I watched all these cases with great interest, and if there was a single failure with any one of these cows to carry her calf the full term, it never came to my knowledge, and with the great majority of them I had personal knowledge that they came through without mishap.

The abortions in my own herd were too numerous to be accounted for on the score of accident, and the failures to breed could not be charged up to feed, however it might have been with the original miscarriages. I think it safe to say that not only the individual cows, but the herd itself was "infected", and if there ever were conditions favorable for transmission of the disease by the male, they existed on my premises at that time.

Jefferson County, Wisconsin. C. K.

Our friend and neighbor (Mr. K. lives in an adjoining town) makes out a pretty strong case in the negative, and it is quite impossible at this distance in time and in the absence of many material facts to account for the exemptions he relates. What we don't know—and in this case the "we" includes others as well as the editors—what we don't know about abortion is incomparably more than what we do know. The indications are that there are several causes which may produce it; but what they are, how they became operative, and how they may be limited, have not yet been fully determined. It is however, fairly well, if not conclusively, established, that abortion is sometimes caused by a specific germ, and that the introduction of this germ into the vagina of the dam will frequently produce abortion. This has been demonstrated experimentally, and the multitude of instances where abortion has followed service by a bull having access to infected cows, seems to justify the conclusion that the germ may be conveyed in this manner. That the trouble does not follow every service, that in a given case, like the one cited, there is exemption in every case, does not prove that in other cases and under other circumstances the disease is not communicable as stated in our previous article.

How Oleo is Working in England.

The following is an extract from a letter in the *Live Stock Journal*, England:

In going into a retail butter establishment a few days ago, I was informed by the manager that they sold their butter at a low price to draw the margarine buyers into the shop, as it was on the margarine that they made their profit; in fact, he advised me to give up butter-making and go in for margarine, as it was fast knocking butter out of the market.

How much of the same work there is going on in this country, and how long before it will knock butter out of the market entirely, is a very interesting question to the dairyman, at the present time. That it can and will do it if permitted, there is no question.

Forty million dollars of capital can and will brush aside the weak efforts of individual producers of butter. Nothing but combined, united effort will ever succeed in putting oleo in its right place, and keeping it there; and until it is done, oleo sold for and at butter prices, will take the place of the dairy article,—taking its profit as well as name and place.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

GLOSSARY.

The terms used in this department of HOARD'S DAIRYMAN have the following significance:

RATION.—The total allowance of feed for twenty-four hours.

DIGESTIBLE NUTRIENTS.—That portion of the organic matter which can be digested by the animal and does not pass off through the bowels as excrement.

PROTEIN.—That part of the digestible nutrients which goes to the formation of lean meat, ligaments, hair, horns and the casein (or curd) of milk. It is generally believed, also, that protein may be, and many times is, converted into the fat found in milk. The basis of protein is nitrogen, hence the protein elements are frequently termed the *nitrogenous* parts of the food. They are also called *albuminoids*.

CARBOHYDRATES.—That part of the digestible nutrients which is the primary source of sustaining animal heat and furnishing the power for keeping the animal mechanism in operation. They are composed of the woody fibre of the plant and grain, and the starch, sugar, gums, etc., and in the published tables of chemical analyses are usually subdivided into the terms *crude fibre*, which is the least digestible portion of feeding stuffs and *nitrogen free-extract*, so-called because it does not contain any nitrogen.

ETHER EXTRACT.—That portion of the digestible nutrients which may be dissolved out of the food stuffs by ether. It is frequently called *crude fat*. Whether fat is actually digested and thus passed on into the circulatory system in a changed form or whether it is simply separated from the other elements and always maintains its identity is an unsettled problem. It can be used by the animal for maintaining the body temperature, and for this purpose is from 2.2 to 2.5 times more efficacious than the carbohydrates. It is maintained by some, that the fat in the milk comes, largely, from the crude fat in the food, but ithas been demonstrated that it is not absolutely necessary, for this purpose.

CHAFFING HAY, STRAW AND OTHER FODDER.

Sometime when convenient, and you have the subject matter at hand, I would like to know through the DAIRYMAN what advantage there is in cutting hay or straw, and after wetting, mixing the ground feed with it? It has been my practice, but some good dairymen tell me I am wasting time and labor. I know it is quite generally done in English dairies, and they usually "pulp" their roots, and mix with "chaffed" straw and ground feed, and let it stand 12 hours, before feeding. A. H. K.

Coupeville, Wash.

Perhaps the best reply that could be made to the above inquiry would be to suggest that the cows themselves be consulted. True, they cannot set forth in words the exact reasons why they prefer food prepared in one way, to the same materials put before them in different forms, but that they have a choice, they are able to make very manifest. And there is no better rule for feeding than to consult the preferences of the animal. Probably with the best quality of early cut hay, the cow would have little choice between that which was long and that which had been chaffed. On the other hand, if the hay should chance to be a little over ripe (as is the case with straw) or a little dusty or musty, then chaffing and wetting and heating would render it more palatable, and the addition of the meal make it more appetizing. And whether we feed cows for milk or steers for growth, the profit comes from the food eaten in excess of the demand for simple maintenance.

Again, as we have said so often in these columns, the highly concentrated grain feeds, like corn meal, cotton seed meal, gluten meal, etc., need to be much diluted or extended in order to be thoroughly digested.

TO FIND THE STRENGTH OF SULPHURIC ACID.

How can the correct strength of sulphuric acid be obtained? A SUBSCRIBER.

Institute, Wis.

The actual strength of sulphuric acid is obtained by the use of an instrument called a hydrometer. With it the specific gravity of the acid is taken and from the figures thus found the strength of the acid is ascertained.

As the use of such an instrument requires previous training to do accurate work, it is better to require the seller to guarantee the strength of the acid purchased. It should have a specific gravity, for testing milk of 1.82 to 1.83.

WEIGHT OF CREAM.

I am purchasing select cream by the gallon, but weigh it in and desire to know how many pounds I should figure per gallon. Will 8½ lbs. be as near as I can practically get at it, or should I use a fraction, and what is the fraction? C. J. W.

Brighton, Colo.

The only proper way to buy cream is by the test, as the difference in the weight of a gallon of rich or poor cream is too small to indicate the richness of the cream. The difference between 20% and 50% cream is less than half a pound in a gallon. You should procure the necessary apparatus for testing cream by the Babcock method and test every sample; otherwise you are doing yourself or the patron a decided injustice. Cream containing 20% fat weighs 8 46 lbs. per gallon, and that containing 30% fat, 8.34 lbs.

BOOK ON CHEESE MAKING

What is the best work published on "cheese making" at the home dairy? I wish to make A No. 1 cheese, suitable to compete with creamery cheese. Extra country cheese as well as extra country butter, sells better here than factory. WM. E. S.

Henry Co., Md.

Cheddar Cheese Making, by John W. Decker. It can be obtained from this office for $1.00 post paid.

WHEY FOR CALVES.

I would like to know your opinion of whey for feeding calves; if it is as substantial as skim milk. Also if it is necessary to re-enforce the whey, what should be used? I have a dairy of 60 cows and 120 acres of alfalfa under irrigation. G. H. W.

Newman, Cal.

Whey is a very poor food in comparison with skim milk because its most valuable constituent, casein, has been removed. The ingredient that remains, milk sugar, is a carbohydrate, and belongs to the class of cheapest food products. Besides the milk sugar, there is present a small amount of albuminoids, about .8 per cent.

In cases where whey is plenty and can be obtained in a perfectly sweet condition, it can be used to feed calves if the necessary albuminoids are added in the shape of oil meal or other feed rich in protein. It is absolutely necessary that the whey fed to calves be sweet and that all vessels holding it be scalded daily so as to be free from any sour taint. It is not a first-class food even when sweet and can easily be rendered worthless and even dangerous by allowing it to sour or feeding it in dirty vessels. For a calf 10 days to 2 weeks old add one-fourth of a pound of oil meal, old process, to a gallon of whey. When 3 to 4 weeks old add a quarter of a pound of bran or ground oats in addition to each gallon of whey.

MILL FEED.

I forward you under another cover a sample of mill feed, which can be bought for $12 per ton. Many farmers in this locality claim that their cows do well on this feed, yet the majority of our farmers have Prof. Shaw's ideal cow, and of course one cannot safely follow their ideas and expect to succeed in the dairy business. We can purchase bran at $17 to $20, and if this mill feed has any merit would like to know.

Kindly forward me a ration of oat and timothy hay mixed, roots, bran, or the mill feed. We feel that it would not pay to experiment, so kindly advise us.

Spinaway, Wash. PHIPPS BROS.

The "sample" seems to contain a little of everything that could be taken out of a lot of wheat, preparatory to making it into flour.

A partial list would be weed seeds, dirt, shrunken wheat, oat hulls and chaff. It has considerable feeding value, but there is no way of determining its comparative value, except by experiment.

We suggest feeding, say 16 pounds of the mixed hay, 20 pounds roots and 10 pounds bran. The amount of mill feed to substitute in whole or in part for bran we cannot estimate.

Which is The Better Cow?

We had not intended to continue the discussion of the above question, but the following opinions are so much out of the ordinary that we feel sure the majority of our readers will enjoy them.

ED. HOARD'S DAIRYMAN:—As regards the cows in the number dated May 5th, I judge them by temperament, so will put the glossary of temperament first, in scoring points of the better cow.

Vital Temperament—Or nourishing apparatus, embracing those internal organs contained within the trunk, which manufacture vitality, create and sustain animal life, and re-supplies those energies expended by every action of brain or nerves.

Mental Temperament— A superabundance of the power which embraces brain and nerves, the exercise of which produces feeling, sensation, etc.

Motive Temperament—Embraces bone, muscle, tendons, etc., which give physical strength of bodily motion, and constitutes the frame work of the body, enabling it to endure continuous physical motion.

For convenience will name the upper cow on the page, Rose; the lower one, Gem.

Rose has a mental-vital temperament, combining all points named under mental and vital; in addition, the following points through combination: Slow thinker, easy, loving disposition, but little curiosity, looks out for her share of forage (a go-easy disposition.)

Gem has a motive-mental temperament, combining all points in motive and mental, and in addition through combination, intellectual vim and force of character; to think is to act, great curiosity, likes a long tramp through the country (an uneasy disposition).

With a careful study of glossary, together with the forms of Gem and Rose, you will be able to find all the producing cows in the United States, (barring accidents and casual deformities, together with mismanagement) you will decide with me that the cow having the strongest internal organs, well bunched, and well supplied with material to work on, together with quiet disposition, submissive under the forced conditions the dairyman places her in, little curiosity to wander and see the country, a voracious appetite, and good sized, well spread udder, will be a good breeder and all around a satisfactory cow in the dairy.

Rose fills nearly all these requirements, so is the better cow of the two, for the following reasons: Short in body, forcing a bunching of organs, thereby overcoming loss of power by friction. It is a law in mechanics "the farther the weight to be moved is from the power, the greater is the loss of power by friction." So blood from digestive organs near the lungs and lung blood a short way to the udder, makes large quantity of milk more easily furnished, so can continue longer without undue wear of organs. Excess of power is utilized in preparing more material for production, with small expense to vital organs, and as her limbs are weak and lacking in bone and tendons, she walks more deliberately and shorter distances, so saves power to apply extra motion of jaws in grinding food. Her generative organs are near the fountain of supply, so are active and productive, seldom produce nymphomania for lack of well grown germs; her curiosity goes no farther than a hay stack or tub of meal; she cares very little about the size of pasture or number of gates; would follow other cattle from love of company, but not to stampede; is tender of flesh and sensitive of nerve; loves her master, would not kick without notice. Is all around an ideal dairy cow.

Faults she has, of course. Too fine to have very large teats, or to endure much exposure of climate; will soon resent rise and fall of temperature. Small bone material would affect wear of teeth, so I would expect that the great quantities of food masticated would wear teeth unduly and cause premature old age. But her master will not ask her to rustle much in cold and wind and pick feed in a stock field mid snow and storm; he will give soft food and protect from pinching temperatures, and if he cannot do so, better take the cow Gem.

Gem can endure extreme changes, and if allowed to walk and run, can keep up bodily heat, could live on a range and outwit the cunningest coyote, would know where all the tall grass grew when a deep snow came, or every tree sheltered spot when the wind blew, would take all the best places, if she was able, for herself, and would really mourn for more, would walk miles for water and miles more to find a lush spot of feed, or battle with strange cattle, could produce quite a quantity of milk, and would not be a No. 2 dairy cow if a person could keep her thoroughly contented, and stop so much waste of vital energy in a direction of little use to a dairyman. A ranchman would buy her on sight, as he wants a cow to be able to rustle for herself and calf, not bred too often, so as to allow the calf to be a year or two old before weaning, to ensure its knowledge of the range, and its vicissitudes before being crowded aside—and because of her bony, long, lank build an old-time farmer would have selected her to milk and raise work oxen from. She is not a failure as a dairy cow, but as a type must score second. (MISS) M. L. E.

San Dimas, Cal.

ED. HOARD'S DAIRYMAN:—Kindly accept a novice's criticism, one who never owned a cow, but nevertheless a great admirer.

Rose of the Quartiers has a head that is unusually commendable from the muzzle to the ear tips, viz: muscles of the jaw, the mouth and formation of nostrils. The camera fails to show any brightness of eye, but a cow that can pose or hold a position as this animal is doing, having such a business look, certainly has the eye for business. A typical throat and neck, shoulders and forelegs very fine. The lungs deserve special mention, but the girth of the stomach, with general proportion of stomach is the real striking feature of this animal.

Rose has an apparently rugged constitution, which backed up by such a stomach indicates wonderful reserve.

The hind quarters are worthy of special mention, being built on a very liberal plan, the framework being built to order apparently.

The front udder and milk veins are especially worthy of mention, the veins having an elastic tortuous course, and very well developed. The front udder it certainly up to the other fine points, extending forward, square, well placed and plenty of it.

The hind udder is quite perfect, coming well back and rounding in at the proper point.

The tail well set, extending from a well placed, strong spinal column, high arch.

Rose of the Quartiers is a typical animal, but space will not admit of comment at length. Villet's Gem does not appear to have the constitutional make up to carry out the intention of her udder formation. A peculiar situation. An apparently fine udder attached to an ordinary high bred animal.

The above criticism is not from practice, but theory entire. Have heard a great deal of talk, but never supposed to know a good one. G. M. L.

Fremont, O.

ED. HOARD'S DAIRYMAN:—I am not a judge of dairy cattle; I wish I was. I am trying to learn; for that reason will be glad to have you pass on my judgment, which awards first place to Rose of the Quartiers. I like her countenance, her whole head and neck, good withers, good breast, good depth from withers to breast, large barrel, spine prominent, prominent milk veins, especially good fore udder, broad across hips; could hang your hat on hip bones, in fact rather coarse in her general make-up; high arching flank, and not least in my estimation is size. I am of the opinion that size is one of the important factors which enter into the general make-up of a *profitable* dairy cow.

Ohio. W. J. LEHR.

ED. HOARD'S DAIRYMAN:—I think Rose of the Quartiers is the better looking cow. She more nearly reaches the ideal dairy cow than does Villet's Gem. She has a wedge shape as seen from side view. Straight, firm back, long face, mouth and nostrils seem large, neck thin and nice length, legs nice length, chest girth seems large, denoting vigorous constitution, stomach deep, udder front carried well forward, back not attached as high as might be, milk veins long, large and tortuous.

Villet's Gem lacks depth of stomach, chest seems drawn up, front udder does not reach forward enough, legs a little long. She does not look to me as rugged nor of as mild a temperament as her mate, Rose of the Quartiers. JOHN VICKERY.

Ohio.

ED. HOARD'S DAIRYMAN:—My choice of the two cows, illustrations of which appear in May 5th number of the DAIRYMAN, is Rose of the Quartiers, for the following reasons:

1st. She shows more refinement, having a better shoulder and neck, which droops nicer, has a larger muzzle indicating greater powers of digestion, and seems more dished in face and broader between her eyes, denoting greater intelligence.

2nd. Her paunch is greater in proportion to the rest of her body and her milk veins being very prominent and tortuous surpass her rivals.

3rd. Her front udder development is better than her rival's, and her teats seem wider apart showing four large quarters.

4th. She has better thighs, more incurving, showing less tendency to beef, and she is very long back of hip bones and appears to be quite wedge shaped.

5th. She has a better back bone, her lines being straighter from shoulder to pelvic arch, and the latter being more prominent, and showing a better spine back of her arch.

6th. She has shorter legs, and being of a more compact build, should wear longer at the dairy work, and should make milk or butter at considerably less cost than her rival.

7th. I judge the respective merits of the two cows largely by the ideal of a model cow formed from a close study of the best authorities on the best type, but this ideal has proven, in my experience as a dairyman, to almost universally produce a profitable cow. In the past four years I have owned fully 150 milk cows and heifers, and my plan of weeding out unprofitable ones gave me a splendid opportunity of testing these theories. I am buying up a young herd of Jerseys now in order to begin with the heifers at the first stages of their development, in order to test the value of good training, as well as good types, and expect in this way to lay the foundation of a herd superior to anything I could buy already developed. Persistency at the pail counts for so much, that I want to fix that habit on all of my cows, and I have learned that the first year of a heifer's milk production, confirms the habits she will have in all future years. One of the best young cows I ever owned was dried off too early by a mistake as to date she was due to freshen again, and although combining almost all of the good points of Rose of the Quartiers, with greater refinement, and smaller but broader head, she persisted in after years in resting fully three and one-half months before calving.

Pennsylvania. OTTO GREIF.

Pencilled Pot Pourri.

Bob Veal in New York.—Adulteration of Cattle Feed.—Process Butter.—Selling the Best Cows.—Geneva Experiment Station Herd.—Making Good Dairy Products.

ED. HOARD'S DAIRYMAN:—One of the laws passed by our last legislature, but which was not signed by the Governor till after the adjournment, is known as the "Bob veal law." Considerable turmoil and rejoicing have been indulged in, in some quarters, because of it, together with the fact that, as one of the results, a half hundred or more dealers in the three-days' old "slippery stuff" are about to be brought to bay. Now, why did not the framers of the law add a codicil which would twist the necks of the scoundrel farmers who furnish the "veals"(?) to the dealers?

Why should they be left to furnish another gang of dealers with more "bobs," and do it *ad libitum*, *ad nauseam*, while only the dealers are prosecuted? They may easily be hunted down, as their names and addresses are known at every express office from which their "wares" have been shipped.

If it were not for these dishonest, greedy scoundrel farmers, no "bobs" would be shipped; no arrest of dealers; and no expense incurred by the Department of Agriculture, to hunt down and prosecute these men. Surely one's first thought is: "Why should these farmers escape the payment of a just penalty." What sort of law would one be that allowed illicit distilleries and open dens for the manufacturing of counterfeit money, but only provided punishment for the dealers in the whiskey, and the "shovers of the queer?" I, for one, can see no difference.

If disease is to be cured, the *cause* must first be removed. If bob veal shipments are to be stopped, the farmers who furnish the carcasses must first be lassoed. Just so with process butter, filled cheese, stuffed fruit packages, and, as a rule, adulterated maple sugar. They are all "onto the game." Greed is the cause, and the disease is spreading; and, if it keeps gaining as it has during the last decade, it will require a Diogenes and lantern at high noon, in every town, to find an "honest man."

We used to say "honest farmer," but that was some time since, during which several of them have died.

Assemblyman D. P. Witter, of Tioga Co., and a subscriber to the DAIRYMAN has made a good record by introducing and forcing through the legislature a bill which the governor has signed, prohibiting the vending of adulterated cattle foods. Mr. Witter is himself a large dairyman; has been on the staff of Director Dawley, as a speaker at farmers' institutes; is familiar with the feeding values and analyses of all our cattle foods, and was, therefore, just the man to step in and drive the entering wedge in this move to stop the

"Necessity Knows No Law."

But a law of Nature bows to the necessity of keeping the blood pure so that the entire system shall be strong, healthy and vigorous.

To take Hood's Sarsaparilla, the great blood purifier, is therefore a law of health and it is a necessity in nearly every household. *It never disappoints.*

Tired Feeling – "I had that tired, dull feeling, dyspepsia, headaches and sinking spells, but Hood's Sarsaparilla made me a new man. I never was better than now." JOHN MACK, Oskaloosa, Iowa.

Rosy Cheeks – "I have good health and rosy cheeks, thanks to Hood's Sarsaparilla. It builds me up and saves doctor's bills." MARY A. BURKE, 604 East Clair Street, Indianapolis, Ind.

Hood's Sarsaparilla
Never Disappoints

Hood's Pills cure liver ills; the non-irritating and only cathartic to take with Hood's Sarsaparilla.

Not a Preservative but a preventive. If you would have your milk keep sweet longer and be free from all objectionable odors, use a CHAMPION MILK COOLER-AERATOR. It does its work perfectly and its use doesn't violate any law—it doesn't need to be used on the sly. Our book "Milk" is free.

CHAMPION MILK COOLER CO., 67 Main Street, Cortland, N. Y.

adulterated cattle food swindle, which is being practiced by almost every miller and feed dealer, to a greater or less extent, in the state.

So extended has this fraud become that it is almost impossible to go to a feed store and buy pure cattle foods; and it is hoped that Mr. Witter's law will reach these dishonest dealers and shut them off.

The interim between the signing of the bill by the governor, and the date of its becoming an operative law, January 1, 1900, will give the holders of adulterated stock, time to clear it up. If any of them are caught selling it after that date, it is more than certain that Mr. Weiting's scouts will have them where their hair is short.

Another law is that relating to process or sterilized butter, and which prohibits its sale. Doubtless, it will prove to be a black-eye for the filthy people on the farms who furnish the original "base" for the stuff, and which the cross roads and village merchants buy, paying one price for all grades, because they "do not want to lose the customer."

When these women who weekly make and swap this villainous compound for "kerosene, kodfish and kalico" at these stores, find their markets closed, they will either learn how to make butter instead of grease, or else send their milk to a cheese factory or creamery.

One thing is sure: The merchants who have been buying this stuff and selling it to professional packers are going to find their markets closed, so that, no doubt, they will either buy the so-called butter and pay for it according to grade, or else refuse to buy it at all. The latter plan would stop its manufacture and save a *quantum* of profanity on the part of some poor deluded mortals who buy it and take it home, to be eaten from the family table.

Will the day ever come when the average dairyman will refuse, for a slight additional price, to sell his best cows? A few days since, a buyer from Connecticut, came into town and selected a number of the very best cows in this locality. I saw them being "rounded in," at the village hotel sheds, and could not refrain from asking some of the sellers why they had kept these cows through the winter, and now, when cheese was selling for 9¼ to 9½ cents, they were selling their very best cows.

Of course, they offered various reasons. One man's cow had not yet freshened, and he thought he had enough without her; another wanted the money; while another sold two to get rid of one. One of the two latter was a very high grade, if not a full blood Jersey, just fresh, which her owner said was making nearly 10 pounds of butter a week, on dry feed. "What did you get for her?" I asked. "Well, I'll tell you, I let her go because I wanted to sell that one. I got $80 for the two; I called her $50, the other one $30. Couldn't sell the other one, without I let the Jersey go. Guess I missed it, as I've got to go out and hunt up another cow. Haven't got one of any kind."

Presently, after the man had been paid, a neighbor of his offered the buyer $60 for the Jersey, but he smiled very sweetly and remarked: "Guess not; but, if you fellers want anything in the bar-room, go in, I'll settle."

I said to the man who sold the two cows: "It would have been money in your pocket, situated as you are, could you have done no better, to have given the $30 dollar cow away, and kept the Jersey, as I think the Jersey is worth more than the price you got for both." He made no reply.

Readers of the DAIRYMAN, or some of them, will recall my article in the paper about a year since, descriptive of the Jersey herd which Mr. Dawley and Mr. George A. Smith selected near Fayetteville, for the State Experiment Station Farm at Geneva. While in Geneva last spring, I visited the station and looked over the herd, Mr. Smith accompanying me. Pointing to one of those cows, he said: "There is one of the herd. She is 'Osborn.' I have forgotten her number, but here are a few figures showing what she is doing.

She dropped her calf, February 6th, having been dry about three weeks.

March 11th she gave 40 pounds, 10 ounces of milk, which Babcocked 5.6% fat, and which shows that we made no mistake when selecting her for the station herd."

"What is her ration?" I asked.

"Well she is now eating 40 pounds of good ensilage, 6 pounds of mixed hay, principally clover, 10 pounds of sugar beets, 3 pounds of wheat bran, 2 of malt sprouts, and 1 of linseed meal. Possibly as she advances in lactation, we may increase, decrease, or change somewhat the formula of her ration. At present however, she is doing extra well producing, as she does, about 2¼ pounds of butter fat per day. If we add 15% for moisture and salt, which is 5% less than the World's Fair scale, we shall have 17 pounds of butter in seven days."

I said "I consider her an extremely good cow, and one whose record clearly showed that, when the cowology of a Dawley and Smith were combined, no doubt ought to be entertained as to the results of any of their selections.

It pays best to make best goods—butter and cheese—and to exhibit and advertise them whenever opportunity occurs. *Some* one is sure to want them, and is willing to pay good prices. The man or woman who makes inferior or second quality of dairy goods, stays away from fairs, institutes and dairy exhibits, then swaps them for groceries at the village store, while they may pride themselves on being classed with the "great unwashed", will never cut much ice, or be missed when they go over the divide; while the one who goes to the front with his products and shows them to the lookers on, is sure of his reward, when it is seen they are of the best.

Mrs. F. E. Dawley, of Fayetteville, New York, is of the latter class. She made, with her own hands, butter and cheese, then had the courage to show her handiwork at the meeting of the State Dairymen's Association, at Gouverneur, last winter, where they were seen and admired by thousands of people. As a result of her ability and pluck, her products scored among the highest, some of them reaching the highest possible figures, 100 points. Seeing this, a dealer just starting a high-class retail dairy product trade in Cortland, wrote her, in part, as follows: "I am only just trying to start, in a small way, a retail butter, cheese and egg business here. If I succeed in getting such a place as I want, I intend to put upon the market just such a class of goods as you make, and also such cheese as Mr. H. E. Cook makes. I want the finest butter and cheese that I can get. I have been a cheese maker during the last eighteen years, and have met a good many of the gentlemen on the state dairy force, including Mr. F. E. Dawley, G. A. Smith and H. E. Cook, and I congratulate you upon your high score of butter and cheese at the State Convention at Gouverneur; and I think the time is right here, when the people are going to demand, for home consumption, such goods as are manufactured by the people on the institute force; made from good, clean, inspected milk, with the quality and purity of the goods guaranteed; and, if I open a retail trade here, this spring, you will hear from me again, as such goods as you manufacture are such as I want to place before the people."

When one comes to know that Mrs. Dawley did all the work of making the goods she exhibited—from the running of the "Humming Bird" separator, to the packing and printing of the pound prints of butter, and from the placing of the milk in the cheese vats, to putting it in its jars or pots ready for exhibition, in view of the honor conferred upon them by the scores at Gouverneur, and the writer of the foregoing letter, surely he must admit that Mrs. Dawley is entitled to take the highest honors, when lodge opened in that degree. C. W. JENNINGS.

Bellieville, N. Y.

Concerning Stave Silos.

ED. HOARD'S DAIRYMAN:—In your paper of May 19th, is a long article copied from the Cornell University Bulletin, which in one sense has your endorsement. You give it a great deal of prominence and virtually endorse the statement made in that article when you say that a silo made out of staves need not be beveled. In fact, the article itself says that it is better if it is unbeveled. It may be said by you that "it is our province as a paper to publish anything that is the greatest good to the greatest number of our readers." We hold of manufacturers like ourselves, or manufacturers of feed cutters, silos or anything else, that their existence as manufacturers depends upon our turning out a first-class article and it would naturally follow that if we are turning out a first-class article it is because we believe it policy and best for the trade that this be done and can only arrive at such a conclusion after quite a little investigation.

We have tried to investigate and find out what was the best for us to make and the further we go into this matter, the more we feel that the better a silo can be made, the better it is for the man who makes it and any article like that published doesn't change our mind any. We confess that it seemed to us as though that article was inspired largely by this feeling which seems to be so prevalent all over the country, that we must get something cheap; we must get something just as near costing nothing as possible. People never got something without they paid for it, and it is just as true in the matter of silos as it is in anything else. There are many localities where silos are not used at all, simply because the first ones were built square, they were not half made at that, they bulged between the corners, the ensilage hung in the corners and spoiled, and while even a square silo, properly built and the ensilage put in in a proper manner will keep it in good shape, yet it never kept ensilage as sweet as a round silo properly built.

We write this because this article from Cornell advocates a make-shift in our judgment, and your publishing the article virtually indorses it. WILLIAMS MFG. CO.

Butter Milk from Skim Milk.

In a late issue of *Home and Farm* a number of inquiries were printed as to the feasibility of making good butter milk out of separator skim milk. As there seemed to be some doubt about it in the minds of some of our correspondents, to set that doubt at rest, the DeLaval separator people have sent us the following communication in regard to inquiries about making butter milk from separator skim milk:

"The usual way of treating this skim milk for making butter milk is to set the milk after it is separated in a can or vat and mix with it what is called a starter, or, in other words, a small portion of butter milk. This has a tendency to sour skim milk, and this should stay in the can at least twenty-four hours. When the milk has soured, put it in a churn and churn it for one-half an hour to an hour.

"By treating the milk in this way you will have excellent success in making butter milk. Your idea of mixing the butter milk is correct, and the temperature stated, 75 to 80 degrees, is about right. We know of a great many that are treating their milk in this way, and are having entire success with the butter milk."

This carries out substantially the instructions as I have given them, and should save to the Southern butter maker all his skim milk for a market always anxious to get good butter milk.

Keep Your Youth

If you are young you naturally appear so.

If you are old, why appear so?

Keep young inwardly; we will look after the outwardly.

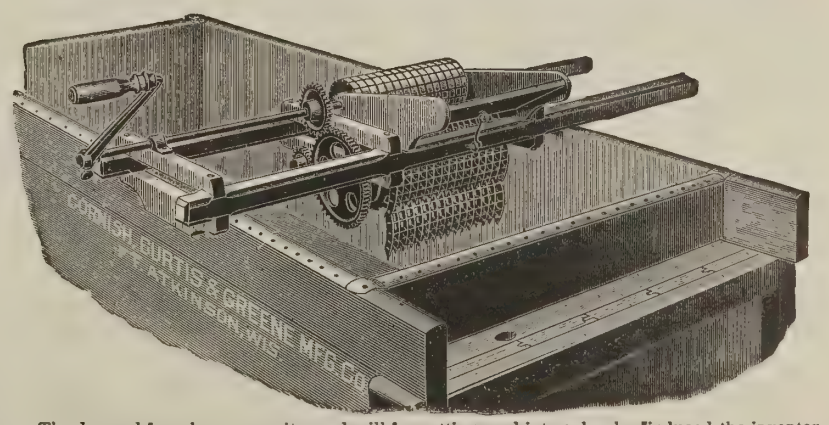
You need not worry longer about those little streaks of gray; advance agents of age.

Ayer's Hair Vigor

will surely restore color to gray hair; and it will also give your hair all the wealth and gloss of early life.

Do not allow the falling of your hair to threaten you longer with baldness. Do not be annoyed with dandruff.

We will send you our book on the Hair and Scalp, free upon request.



Write to the Doctor.

If you do not obtain all the benefits you expected from the use of the Vigor, write the doctor about it. Probably there is some difficulty with your general system which may be easily removed.

Address, DR. J. C. AYER, Lowell, Mass.

Kasper Rotary Curd Mill.

The demand for a large capacity curd mill for cutting curd into cubes has induced the inventor to bring out the Kasper Mill. In construction the mill consists of a rotary cylinder made of knives in the form of cubes. Against these knives a wooden roll revolves with indentations to fit the knives of the cylinder; the curd being fed into the hopper is forced through the openings in the cylinder by the wooden roll. The cylinder is made in three sections hung on hinges, and, as it revolves, each section as it comes to the lower part of the cylinder, opens and allows the curd to drop into the vat, the section closing again as the cylinder revolves.

It is estimated that the curd from 7,000 lbs. of milk can be cut in from 7 to 10 minutes. The mill operates easily, being light running and adjustable to either hand or belt power. Simplicity of construction, durability and ease of cleaning are some of its principal features. All parts being galvanized or tinned prevents rusting. Weight of the machine complete is about 38 pounds. List price, $25.00.

A Stave Silo Experience.

ED. HOARD'S DAIRYMAN:—I took the model you published for building a silo from the Purdue (Ind.,) Experiment Station last fall and wish to tell you the result

In the first place, I had planted twenty acres of black cow peas and they made a very large crop, a great deal heavier yield than any clover I ever raised, but we had showers so often that I could not cure them for hay.

I believed I could soon build a silo of such 2x4 lumber as I could buy at our lumber yard, so I made a trench 18 inches deep, built a brick foundation, 2 feet high, in a circle 24 feet across, set four 4x6 scantlings to put the end of hoops through, to draw tight with screws. We then took two lengths of 2x4, half 14, the other half 16 feet long, and spliced in middle alternately as directed; that made it 30 feet high.

Set it close to barn and made a small room between the silo and barn to throw the silage into. Covered it all with galvanized iron, filled it with cow peas and field corn about half an inch long run through a cutter and up a 40 foot elevator and tramped it down well in the silo.

I have never fed silage before, so I can not tell if that is better than all corn silage, but know that it kept well, with the exception of a little, where there were small cracks that we could not close up so that daylight could not be seen through. We turned the nuts on the five-eighths iron rods or hoops, until the washer and nuts sunk into the wood, the thickness of the nut, and still daylight could be seen.

I wet the inside well with water when we filled it but it did not swell enough to make it perfectly tight. We had a few feet of cut corn fodder on top and there we found a foot of mold opposite to the crack, but where peas were mixed with corn it was not more than three or four inches thick.

The spoiled was but a very small per cent and we did not give it to the milch cows but to young cattle. It seems that a perfectly tight silo will keep the silage all right and it was a much better feed than corn fodder and hay and I have a strong belief in mixing cow peas with corn for silsge.

I have now taken off the nuts and washers and put on inch thick elm plank pieces and turned the nuts a great deal tighter but still can see some daylight between some of the staves. I remember reading of some one in the DAIRYMAN that plastered his stave silo with cement. I would like to know if he puts slats on or what way he could get cement to fasten on. It would not stick on smooth staves.

I like the silo very much and also the cow peas to mix with the corn as they give a fine yield and I think help to balance the ration so that less bran need be bought. My cows did better last winter than ever before, the main fault being that I did not have enough silage or oats for them (I had 80). I am now planting forty acres cow peas and if they yield as well as last year I will build another silo on the same plan the coming fall.

I went at it unprepared and did not try to build cheap. When completed it cost me $350 but I do not regret the cost, only wishing that I had built one long since. I have cut and shucked corn as best I could for years and run it through a fodder cutter, thinking to get all the benefit of corn, but there is much more loss and stock does not do as well on it. JOHN PATTERSON.

Missouri.

Butter at 10 to 12 Cents.

At the fourteenth anniversary of East Haddam grange, W. C. Beach of Storrs college Conn, told of a series of experiments made at the college for a year past with its herd of cows.

They were charged $10 a ton for hay, $3 a ton for ensilage, $22 a ton for cottonseed meal, $18.50 a ton for gluten meal and $14 a ton for bran. They were credited with the butter made at 18 cents a pound. No account was taken of the skim milk. The herd numbered 25. The average for the year was 310 pounds of butter at a cost of 14.1 cents a pound. The average cost of keeping for the year was $40 91 a cow. The net profit was $14 89 a cow.

A full-blooded Jersey made 506 pounds of butter. The cost of keeping was $48.80; net profit, $42.28; cost of butter per pound, 9.6 cents. Another made 466 pounds of butter; cost to keep, $44.43, giving a profit of $39.50, butter costing 9.5 cents a pound.

The average of the beef type, four cows, was 221 pounds of butter; cost of keep, $38.12, profit, $1 21, cost of the butter per pound 11.8 cents.

The dairy type, 12 cows, averaged 330 pounds of butter, costing 12 2 cents a pound; the cost of keeping was $22.29, leaving a profit of $18.70 per cow.

The remaining seven cows were lacking in digestive powers and gave an average profit of $8.50 a cow.

Butter Tests at Valley Mead.

ED. HOARD'S DAIRYMAN:—We wish to report the butter tests of fourteen cows and heifers, which have, of late, been made at Valley Mead. Over one-half of these tests have been officially supervised by the Wisconsin Experiment Station, and all of them have been entered and accepted in advanced registry, as follows:

NAME OF COW AND NO. IN ADVANCED REGISTRY.	Age.	Total Lbs. Milk in 7 Days.	Total Lbs. Butter Fat.
Brightest Promise 1463	9 years	464.4	14.652
Aspizanie 4th 1464	7 years	446.7	14.572
Careme 4th Pauline 1465	4 years	394.4	14.690
Careme 3rd Pauline 1466	3 years	382.8	13.974
Mechtchilde 6th 1321	1 years	342.6	13.263
Mechtchilde 7th 1468	2 years	322.2	12.540
Aggie Scholton Mercedes 1319	3 years	411.	12.609
Tirannia 3rd Netherland 1320	3 years	352.	12.455
Tirannia 6th 1467	2 years	335.	11.752
Elgin Belle 6th 1344	1 yr. 9 mos	282.9	10.416
Natsey Lady Baker 1435	2 years	300.3	10.213
Nimpje's Albino DeKol 1434	2 years	294.8	10.309
Athalend Calantha	3 years	304.7	9.78
Daisy Ryanda's Parthenea	1 yr. 7 mos.	226.3	7.10

We think, age considered, the above showing a very good one. None of them had been especially prepared for a test, but were taken off common, ordinary feed, and put in the test. We do not wish to take space here to give their breeding, but Holstein men are familiar, that more famous breeding cannot be found in America. KARLEN & CO.

Valley Mead Stock Farm, Monticello, Wis.

Silos and Ensilage.

ED. HOARD'S DAIRYMAN:—I have been reading with much interest, your description of stave silos, by Cornell University, which I think is very good. I have used a stave silo three years. And after using one that long, would not like to go back to the old way of feeding hay.

The first winter I fed ensilage and hay; the second winter I fed less hay than I did at first, and the third winter I fed no hay at all, nothing but ensilage for roughage.

I find it takes less grain, such as oil meal and corn and cob meal, etc., than when I fed hay, and my cows do just as well on ensilage and grain, if not better, in every way; besides giving more milk, than when given hay and grain. I think ensilage a very cheap food.

I put ten acres of corn in the silo last fall. I fed 27 head of cows all they could eat, gave some to young stock, and the ensilage lasted until grass was good this spring.

I also read, with much interest, the article written by Uncle Fred, telling about his silo being built partly in the ground and partly above the ground.

I built my silos that way—had some trouble with them, and also success. My ground where I built my silos is flat ground, and the water and also the weight of the ensilage broke the bottom of the silos, and let in the water; then I built the bottom of the silos stronger, and had no more trouble. I find it is not hard to keep water in a cistern, but it is hard to keep water out of one.

I like the plan very much; my ensilage keeps better below the ground than it does above the ground. I am going to build another silo this fall, and I intend to build part below the ground. Then above the ground I am thinking of using common two-inch lumber, 4 inches wide by 20 feet long. Set that up just outside the foundation wall. Tighten the rods reasonably tight, build the wall up to the top with brick, laying the brick tight against the boards; cement the inside of the brick wall from the bottom to the top.

I will leave three doors to throw ensilage out of. It seems to me as though a stave silo built the way I have just mentioned, would be perfectly air tight. The only objection I can see is the freezing of the ensilage in winter would cause the cement to crack and come off.

I saw a square silo that was lathed and cemented on the inside. The freezing of the ensilage seemed to have no effect on it, but the sides were not strong enough and the pressure of the ensilage caused the sides to spread and crack the cement.

I find when I first fill a stave silo, the staves swell very tight. In time the ensilage cools off some, then the staves shrink just enough to let in some air. The most near the top. The ensilage is spoilt down the sides to the depth of four or five feet.

Farther down the sides the ensilage has a musty, disagreeable smell. The cattle do not seem to relish it as well as they should. When I am feeding the ensilage that is below the ground it has a sweet smell, and the cattle eat as though they liked it. It seems to taste good to them. My object is to have as little spoilt ensilage as possible. What do you think of my plan? I want to learn all I can. GEO. D. HERRING.

Lee Co., Iowa.

Our correspondent has certainly offered a new suggestion in silo building, and one that would seem to do away with the disadvantage of staves shrinking that is found in the stave silo. If the brick are firmly backed up against the staves so that there would be no chance of movement when the silo is filled, we see no reason why this plan should not be a success.

MECHTCHILDE 1718, H. H. B.

Property of KARLEN & Co., Monticello, Wis.

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—The offering of butter on Monday's Elgin Board of Trade, aggregated 13,620 pounds. Bidding opened at 17 cents but advanced early to 18 cents, at which price the entire offering was sold. The market was declared steady at 18 cents. The sales reported were as follows:

Factory.	*Pounds.*	*Price.*
Red Clover	4,500	18c
Winslow	1,500	18c
Shannon	2 100	18c
Baileyville	1,320	18c
Aurora	900	18c
Cobb	3,300	18c
Total	13,620	

The markets for the corresponding week of the three preceding years were as follows:

June 6, '98, no sales. Market price 15½c.
June 7, '97, 42,840 lbs. of butter sold at 14½@14⅝c.
June 8, '96, 51,540 lbs. of butter sold at 15@15½c.

The New York market was reported firm at 18½ cents. H. C. B.

Elgin, Ill., June 5.

Patents and the Dilution Process of Raising Cream.

ED. HOARD'S DAIRYMAN:—It has come to our knowledge that certain parties are contemplating to collect royalty from farmers, who are using the "dilution process" of cream raising, claiming a patent on the process of dilution. Will you please inform such of your readers as are desirous of using this process, of extremely doubtful utility, that while several forms of cans have been patented, so far as is known, no patent has been issued covering the process of diluting milk with water, as a means of separating the cream. A bulletin will shortly be issued from the Cornell University Agricultural Experiment Station, giving the present status of the whole matter.

H .H. WING, Prof. of Dairy Husbandry.

Making a Pasture.

An Iowa farmer writes:

The best pasture we ever saw in this locality was made by discing oat stuble in the fall, sowing rye and pasturing the rye and second growth oats that fall. In the spring after the ground was dry, mammoth clover seed was sown at the rate of one bushel to eight acres and stock turned in. When the rye headed it was clipped with a mower set as high as possible. This made a mulch for the clover, and also thickened it, and it was a good pasture all the season. The next year it was still better, the cows wading to their bellies in clover. Early in July the clover was clipped with a mower, with the bar set at the highest point, and two tons per acre of fine hay secured, and the stock reveled in the newly growth of clover the rest of the season. We shall plant it to corn this year.

Notes on the Iodide Treatment for Milk Fever.

The new cure for milk fever by the injection into the udder of a solution of iodide of potash is claimed by veterinarians and others to give very excellent results, and already it is becoming recognized in certain quarters as one of the most reliable remedies yet introduced. As already pointed out in these columns, it consists in injecting into the udder (through the teats) one drachm of iodide of potassium mixed with one quart of boiling water, cooled down to 98° F. before being used. Half a pint of this is to be injected into each quarter of the udder. The animal should then be placed in a comfortable position on her chest, and the udder gently rubbed. Her position should be changed every two or three hours, and only one injection is necessary. It should be borne in mind that before the injection is given, the udder and teats should be carefully washed with soap and water, to which a little carbolic acid has been added.—*Farmers' Gazette*, Ireland.

DAIRY MARKETS.

ELGIN, Ill., June 5—Butter—Steady, offerings 227 tubs; all sold at 18c.

CHICAGO, Ill., June 5—Butter—Creamery extra 17½c; firsts, creameries, 16@16½c; seconds, 13½@14c; dairies, selections, 15c; No. 1, 13@14c; No. 2, 12c; extra ladles, 12½c.

Eggs—Fresh, at mark, cases returned, sold at 11@11½c; loss of, cases returned 12@12½c; duck eggs, 12@12½c; goose eggs, 12½c.

Cheese—Full cream, twins, new, good to 11@13c; Limburger, 7@10c; bricks, new, 7½@8¼c.

Bran—In fair request and sold at $10.50@11 per ton.

Cattle—Prices average about 10c lower than the close of last week for all grades of cattle. Best steers showed the least decline, and fed Westerns and cow stuff the most decline. Trade opened slow, but later improved. The extremely hot weather interfered with the prospective beef demand. Exporters bought quite freely at $5.15@5.30, with some at 5.40. The top of the market was 5.50, for 1,321 pounds average. Fed Westerns sold at 4.60@5 35; bulk, 5.@5.25. Missouri fed Texas sold at 4 70@4.95; and straight Texas steers averaging 942@980 pounds at 4@4.55; Texas cows 2.75@3.25; Texas calves 150 pounds, 6, and 886 pound oxen at 2 70. Distillery fed steers sold at 5@5.10, and 1,164@1,334 pound still bulls at 3.20@4.25.

MILWAUKEE, Wis., June 5—Butter—Creamery, fancy prints, per pound, 17c; extras, 17c; firsts, 16@16½c; seconds, 14@15c; imitations, 14@15c. Dairy, selections, per pound, 13@14c; lines, 11@12½c. Roll, fair to choice fresh, 9½@10c. Market unchanged with receipts of 22,430 pounds and a moderate local and shipping business.

Cheese—American full cream, new, choice to fancy, 8@8½c; Brick, new, per pound, choice, 7½@7¾c; Limburger, fall, choice, per pound, 9@9½c; new, choice, 7@7½c; Swiss, drum, choice, 12½@13c; block, choice, 10½@11c. Considerable inferior now offering which has no quotable value. Market easy and quiet; receipts are 4,210 pounds.

Eggs—Fresh, per doz., 11½@12c, cases returned. Receipts 1,159 cases, which together with the increased loss-off caused by the heat, brought about a decline in values.

FOND DU LAC, Wis., June 5—Offerings, 504 Twins and 150 Daisies. Market fairly active at 7½c.

CHILTON Wls.. May 31—The following sales were reported to-day: 200 Twins at 7½c and 400 cases Young Americas at 7½c.

BRILLION, Wis., May 26—Offerings of cheese to-day 823 Daisies, 601 Twins, 448 Young Americas. Market was weak and buyers not anxious to take hold. The quotable market was 8¼c all round, though a few Twins sold at 8½c and a few Young Americas at 8c.

MANITOWOC, Wis., May 31.—Offerings of cheese at the Dairy Board of Trade to day were 300 boxes Daisies, 57 boxes Twins, 600 boxes Young Americas. All offerings sold at 7½c.

SHEBOYGAN FALLS, Wis., May 31.—There were 989 boxes of cheese offered on the call board to-day, and all were sold as follows: 782 cases Young Americas at 8c; 45 Twins at 8c; 77 Twins at 8½c; 85 boxes Daisies at 8¼c; and 10 at 8c.

SHEBOYGAN, Wis., May 31.—The sales reported to day were 420 Twins and 530 cases Young Americas, all at 8c

NEW YORK, June 5—Butter—Creamery, western extras, 18@18¼c; firsts, 17@17½c; state extras, 18c; firsts, 17@17½c.

Cheese—State full cream, large colored or white, choice, 7¾@8c; small white, choice, 8½@8¾c.

Eggs—State, Pennsylvania and western, 14@15c.

FULTON, N. Y., May 29—Sixteen factories were represented with 1,525 boxes of cheese. Large sold at 8c; small at 8⅜c. No butter was offered,

CANTON, N. Y.,—May 29—There were 400 small cheese sold here Saturday at 9¼c. The 1,500 boxes of large cheese were unsold. There were 1,200 tubs of butter sold at 18c.

OGDENSBURG, N. Y., May 29—On the board Saturday, 1 590 boxes of cheese were offered. A bid price of 8½c resulted in no sales, but later on the streets all offerings were disposed of.

WATERTOWN, N. Y., May 29—There were 5,000 boxes of cheese sold, a large majority on the curb. The range was 8¼@8½c for large, the bulk going at 8⅜c.

UTICA, N. Y., May 29—There was another decline in prices to-day, in sympathy with that of the seaboard markets. As compared with last week, the drop from top figures was ⅜c on small white, ¾c on small colored and ⅜c on large colored. There was also an increase in the sales on commission. The ruling price, however was about 2c higher than a year ago. The sales were 95 lots, 5,964 boxes at 7¾ @ 9c.

The transactions on May 31st, 1897, were 7,126 boxes with 7⅝c the ruling price. The transactions on May 30, 1898, were 5,084 boxes, with 6¼c the ruling price.

LITTLE FALLS, N. Y., May 29—Sales were made as below: 47 boxes large colored, 7¾c; 210 boxes large colored at 8c; 100 boxes large colored at 8⅜c; 150 boxes large colored at private terms; 175 boxes white, large, at 8c; 1,290 boxes small white and colored at 8½c; 2,590 boxes white and colored at 8¾c.

PHILADELPHIA, Pa., June 5—Butter—Solid packed separator creamery, extra, 18c; firsts, 17½c; seconds, 16@17c; imitation creamery, extra, 16c; firsts, 15c; seconds, 13c; ladle packed, extra, 15c; firsts, 14c; seconds, 13c. Print butter, creamery, extra, 18c; firsts, 17c; seconds, 15@16c.

Eggs—Pennsylvania and nearby, 14c; western, 14½c; southwestern 14c; southern, 13@13½c loss off.

BALTIMORE, Md., June 5—Butter—Market steady; creamery separator, extra, 18@19c; extra first, 17½c; creamery first, 17c; creamery imitation extra, 15@16c; ladle extra, 13@14c; western store packed, 11@12c.

Eggs—Market steady; strictly fresh stock, 13@13½c.

DETROIT, Mich., June 5—Extras, 19c; slow sale. Fancy dairy, 13c; active.

Eggs—13½c.

WASHINGTON, D. C., June 5—Market steady, extras, 18½c; firsts, 18c.

NEW ORLEANS, La., June 5—Extras firm at 18½@19c; gathered cream creamery, 17½@18c; No. 1 ladles, 14c; No. 2, 13c. Stocks and receipts small.

NEWARK, N. J., June 5—Market steady, 18½c for western extras. Receipts liberal.

ST. LOUIS, Mo., June 5—Butter—Steady; creamery, 15@18½c; dairy, 12@15c.

Eggs—Lower, 10¾c.

KANSAS CITY, Mo., June 5—Butter—Creamery 15½c; dairy 13c.

Eggs—Fresh, 11c.

BOSTON, June 5—Butter—Creamery, extra 18½@19c; western extra, 18½c; dairy extra, 17c; imitation creamery, 14½@15c; western ladle, 13½@14c; print creamery, 19@20c; box creamery, 19@19½c.

Eggs—Fancy, near by 16@17c; choice, fresh, 15c; Michigan extra, 14½c; western 13½@14c; fair to good, 13@13½c.

CINCINNATI, O., June 5—Butter—Quiet, 18½@19c;.

Eggs—Easy lower, 11c.

Cheese—Steady, good to prime Ohio flat, 9½@10c.

NEW YORK MARKET.

NEW YORK, June 3—Butter—Receipts for the week, 55,726 packages. Exports for the week, 1,977 packages.

Buyers have been very particular in making their selections this week and only the very finest quality has passed at 18½c. Good firsts sold freely at 17½@18c, and inferior creameries have had some inquiry at 16½@17c. New York State creameries were more plentiful and freely offered at quotations. Large lines of extra creameries were put into freezers for later markets.

New York State Dairy sold quick at 17@17½c for finest selections and 14@16c for good to fine lots. Imitation creameries and ladle butter were firm at a trifle advance in prices. We quote: Creamery, extra, 18½c; medium, 17@18c; poor, 15@16c; Dairy, extra, 17@17½c; medium, 16@16½c; poor, 14@15c; ladle, extra, 13½@14c; medium, 13@13¾c; poor, 12@12½.

Cheese—Receipts for the week, 25,886 boxes. Exports for the week, 11,285 boxes.

Buyers had every thing their own way and prices declined fully one cent per pound on the week's business. Exporters paid 8¼@8½c early in the week for finest large cheese, but at the close 7⅞@7¾c were the best prices. Small cheese were in liberal supply and freely offered at our quotations. We quote: Full cream (large colored) extra, 7¾@8c; medium, 7@7¼c; poor, 5@6c; Full Cream (large white), extra, 8@8¼c; medium, 7½@7¾c; poor, 6@7c; Full cream (small white), extra, 8½@8¾c; medium, 7¾@8c; poor, 6@7c; Full cream (small colored), extra, 8¼@8½c; medium, 7¾@8c; poor, 6@7c.

Eggs—Receipts for the week, 76,960 cases. Market less active and prices lower. We quote: New York State & Pennsylvania, 15@15½c per dozen; Western & Northern, best marks, 14@14½c per dozen; Other sections, 13½@14c.

177 Chambers St. DAVID W. LEWIS & Co.

BALTIMORE MARKET.

BALTIMORE, Md., June 1,—Butter—The supply of separator creamery from regular sources has been more liberal since our last issue, and indeed has exceeded the consumptive demand in about the same proportion as the three or four preceding weeks were short of it; and though ordinarily these increased and plentiful receipts would give the receivers more than they could satisfactorily dispose of, at this time, and in the hungry condition of the buyers the placing of the extra supply would impose no great task upon them but for the fluctuations in prices causing great uncertainty as to whether all conditions are now most favorable for speculation in the grass-fed lots. Of the next variety, gathered cream creamery, the receipts have been gradually increasing, and in greater ratio than the quality has been improving, nevertheless the bulk of them have been sold to retailers for current use. The receipts of imitation creamery and ladle packed have been fair and of better quality; the demand is about equal to absorbing all that arrives for sale, and the remainder goes into the freezers on shipper's orders. Exporters have not had much encouragement, and their shipments are confined to samples and regular orders for consumptive demand. There has been the customary business in the blocks and prints, the receivers at the close not carrying over any considerable stock. Storepacked Ohio and W. Va. has been in more liberal receipt, and the demand has been brisk

Creamery Separator, extras, 19c; firrts, 18c; seconds, 17c; creamery gathered cream, extras, 17c; firsts, 16c; creamery, Ohio, extras, 18c; firsts, 17c, seconds, 16c; Iowa & N. W. Ladle, extras, 14c; firsts, 13c; seconds, 12c; Ohio & Indiana Ladle, extras, 14c; firsts, 13c; seconds, 12c; Ohio Storepacked, extras, 12c, firsts, 11½c, seconds, 11c; W. Va. storepacked, extras, 12c; firsts, 11½c; seconds, 11c; Creamery blocks, (2 lb) extras, 20c; firsts, 19c; seconds, 18c; creamery prints, (½lb.) extras, 21c; firsts, 20c; seconds, 19c; Md. Va. & Penna. prints, extras, 19c; firsts, 18c; seconds, 16@17c.

Eggs—While the receipts have been a trifle heavier so far this week, the demand has been fully equal to the supply. All invoices of choice stock are promptly placed as soon as they land. Our market still remains in good shape and steady at 13½c.

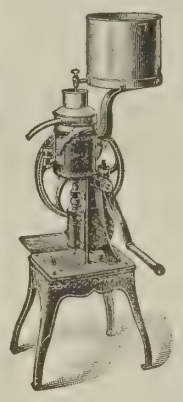
Cheese—All arrivals are composed entirely of new cheese. The supply is quite sufficient for all demands; market quiet and irregular.

N. Y. State—Cheddars, fine, 9¼@9¾c; choice, 9@9¼c; fair, 9c; small, fine, 10; choice, 9½c; fair, 9c; Ohio flats, fine, 9@9½c; choice, 8½c; fair, 7½@8c; Ohio picnic, fine, 10c; choice, 9½c; fair, 9c; Swiss cheese, fine, 10@10½c; choice, 9@9½; fair, 8½.

G. M. LAMB & BRO.
301 Exchange Place.

Latest quotations for fancy creamery—Buffalo, 17½c; St. Paul, 16½c; Minneapolis, 16@16 4c.

FOREIGN MARKET.



BOSTON, June 3.—Cable advices of this date from the principal markets of Great Britain to Geo. A Cochrane give butter markets as barely steady owing to very heavy arrivals of Continental and Irish. The weather is intensely hot and many of the arrivals are badly out of condition. Danish is selling from 19@20½c, finest Irish 18@19c Canadian butter, which is arriving in good order, is in fairly active request at 18@18½c. The home make of butter is large and prevents any good being done in American ladies, which are meeting a slow sale at 13½@14c. Nothing in the finer descriptions of American arriving, but finest creamery, in boxes, would sell, probably, at 17½@18c.

Cheese markets are all tending downwards, and while old is in small compass it is difficult to make over 11c for finest white of American or Canadian September make, while colored is difficult of sale at ¼@⅜c less money than white. New cheese of both Canadian and American are arriving in increased quantities, but is being fairly well cleaned up from 9½@10½c.

LIVERPOOL, June 5—Butter—Finest United States, nominal; good, 65s.

Cheese—American Finest white, 50s; colored, 47s; ordinary new, 46s 6d.

"ALPHA-DISC" CREAM SEPARATORS

The improved "Alpha" disc or divided milk-strata system is used in the De Laval separators only. Strong patents prevent its use in any other machines. The "disc" system makes the De Laval machines as superior to other separators as such other separators are to setting systems. It reduces necessary speed one-half, reduces size of revolving bowl, saves labor and power, enables simplicity and durability, skimming cold milk, running cream of any desired thickness, and insures absolute thoroughness of separation under practical use conditions, which is not possible with any other separator or creaming system.

READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

For Sale—Fifteen h. p. boiler and 15 h. p. upright high speed engine nearly new, also 6 h. p. engine. GEO. WOODRUFF, Adm'r, Janesville, Wis. 14-4

Scour Cure—Stops scours in calves. Large bottle $1.00. A. S. ALEXANDER, V. S., Evanston, Ill. 15-tf

Tamworths, ready to wean, $10 each, or $12.50 delivered. Hermanville Farm, P. E. I., Canada. 32-52

Wanted—At once, a man to work on a dairy farm with milk rout, married man without children perferred. Address, stating wages expected, C. B. DROWATZKY, Tomah Wis.

Wanted—A first-class cheese and butter maker. One accustomed to southern climate preferred. Years engagement; first-class salary. Write for particulars to S. G. FULLERSON, Decatur, Texas.

Exceptionally Low Rates to St. Louis, Mo., via the North-Western Line. Excursion tickets will be sold at greatly reduced rates from all stations, June 19 and 20, limited to June 24, inclusive, on account of Annual Reunion B. P. Order of Elks. Apply to agents Chicago & North-Western R'y. 17-2

Exceptionally Low Rates to Buffalo, N. Y., via the North-Western Line. Excursion tickets will be sold at greatly reduced rates from all stations, on account of Annual Meeting A. A. O. Nobles of Mystic Shrine, to be held June 14 and 15. For dates of sale and limits of tickets apply to agents Chicago & North-Western R'y. 16-2

HOW TO AVOID MILK FEVER.

Valancey E. Fuller, who was Superintendent of the Jersey herd, at the World's Fair Dairy test in Chicago, gives the following as the result of his best experience in preventing milk fever. This dread disease always attacks the heavy milkers. If any of our readers have such a charge on their hands, it might be well to consider what Mr. Fuller says, which is as follows:

"Thirty days before calving, if in summer, keep her on short grass, just enough to keep her working hard to get but a little; give her a quart of bran daily, and about a pint of linseed oil meal (old process), the latter to aid a ready cleaning after calving. If in winter, give her all the hay she will eat, 25 pounds of silage daily, and the same quantity of bran and linseed oil meal as above mentioned.

Three weeks before her due date of calving give her a "drench" of 1 to 1½ lbs. of Epsom salts (according to the size of the cow), one quart of common molasses, two heaping tablespoonfuls of ground ginger, all dissolved in two quarts of hot water; repeat this same drench seven days before she is due to calve, and immediately before or immediately after calving. In addition, give her a handful of Epsom salts, either as a drench or in her feed for the three weeks before calving. I grant you this is heroic treatment but to combat, or, rather to ward off that dread disease, milk fever, heroic measures are necessary.

The object of making the "drench" so large, is this: There is always in the cow's paunch an immense quantity of food; the greater the quantity of water given with any medicine, the quicker and more effectual is the action. "But why give the handful of salts every day?" Have you ever noticed that after drenching, constipation sets in? Constipation tends to fever. That is one of the objects sought, but not the most important.

The direct or contributing cause of milk fever is shrouded in mystery. Authorities differ, but there is a general consensus of opinion that the blood being too thick is the greatest contributing cause. If the blood of a cow that has died of milk fever be placed in water and examined under the microscope, the blood corpuscles will expand to double the size, showing there is too little water and too thick blood. Thin the blood and you go a long way to avert milk fever, and there is no better agent to attain that end than Epsom salts. Do not be deceived because the bowels of your cow are 'loose', that there is no necessity to give a drench. The act of calving will constipate. Thin the blood; thin the blood before calving, and you will best prevent milk fever.

Some object that this is harsh treatment. I give place to no one in my love for a dumb animal. Experience teaches me this is the best practice I know of. I think it necessary, and 'necessity knows no law.' Another objection is raised, and with great force, to the system of cutting down the feed and to the Epsom salts treatment I have advocated, on the ground that it injuriously affects the cow's flow after calving, and doubtless also the richness of her milk. I admit this; it is rough on the cow, but it is necessary, and it is far better to have a live cow, even if you have trouble to bring her to her best work, than a dead carcass. She can be brought to her best work, though it takes a longer time."

How It Affects Iowa.

H. R. Wright, deputy dairy commissioner of Iowa, in speaking of the needed legislation and its effect upon local dairy interests has this to say:

"Practically all of the oleomargarine used in the state of Iowa is fraudulently used. The laws of this state are effectual in keeping out the retailer of oleomargarine, but the practical difficulties in the way of obtaining evidence against the illegal use of a substitute for butter are almost insurmountable. The collectors of internal revenue receive invoices of all shipments of oleo into their respective districts, and insist that the amount shipped into Iowa is very large, but are not allowed by the rules of the department to give information as to the destination of the shipments. Hence the Dairy Commissioner's department must depend npon chance discoveries of hotels and restaurants which are using oleo. The manufacture of any substitute for butter can afford to pay the United States tax of 2 cents per pound and still sell his product at half the price of creamery butter, with profit enough to fight any effort to enforce a state law.

"There is no limit to the amount of oleo that can be manufactured, and since it is almost invariably sold as butter, that means that there is no limit to the amount of 'butter' that may be thrown on the market at any time of the year. It is estimated that the competition of oleo with butter lowers the price of butter from 3 to 5 cents per pound. The amount of butter exported from the state of Iowa added to the amount that is consumed in the state each year makes nearly 200,000,000 pounds, and a matter of 3 cents per pound amounts to something like $6,000,000, which the oleo manufacturers are able to tax the people of our state each year. The production of oleomargarine by the Chicago factories this year is nearly double the amount made last year. Is it not something more than a coincidence that butter is lower than it ever was before in the month of January or February?

The people of Iowa have $25,000,000 invested in cows and creameries, all of which is jeopardized by the unlimited competition of oleo. White oleomargarine is unsalable, though a legitimate article of commerce. Yellow oleomargarine is a fraud and a counterfeit, and is salable only as such. As a fraud and a counterfeit it ought not to be allowed to compete with butter. The easiest way to deal with the subject seems to be to put upon it a prohibitive tax. Hence the movement to tax yellow oleomargarine 10 cents per pound."

Dairy Figures.

At one of the creameries in southern central New York, the other day, one of the patrons had a test made of the individual cows of his dairy, says a writer. He was surprised to find that one of the herd which he had supposed to be an unusually good cow reached a percentage of less than three by the test. She may not have been in good condition at the time the test was made, or other circumstances may have been against her. But if after repeated trials, her percentage should continue low, the owner would be justified in sending her to the butcher.

Let us think for a moment what a low rate cow does for the unfortunate man who owns her. At a test of 3 per cent, it would take 29 pounds of milk to make a pound of butter. It is not likely that she would produce milk enough the season through for a pound of butter per day. We will say she produces three fourths of a pound every day for eight months in the year. This would give us in the neighborhood of 180 pounds of butter for the season. At 18 cents per pound, which is a fair estimate with us, this would amount to $32.40.

To winter this cow will require the equivalent of two tons of hay, worth $10 per ton, or $20 for the season. Her pasturage is worth for the eight months she is out, at a low estimate, $6. She will consume not less than $5 worth of grain and more if she be allowed it. This will bring her keeping up to $31 for the season, leaving $1.40 to pay expense of milking and care. I have said nothing about the skim milk, the manure, or the calf she may produce, because I believe I have placed the expense of keeping much below what the facts will warrant.

While my neighbor was caring for, milking and feeding this cow he might have been bestowing his labor upon one which produce at least 100 pounds more of butter for the season, thus adding $18 to the right side of account, or more than twice as much as he really did realize from the 3% cow.

What are these figures worth to the man who wants to succeed in his chosen calling? It is not difficult to see through this millstone.—*Ex.*

Building Up a Special-Purpose Herd.

ED. HOARD'S DAIRYMAN:—I have been an interested reader of the discussion between the DAIRYMAN and the *Gazette* as to the respective merits of the dual-purpose and the special-purpose dairy cow; and although I was neither born nor reared a dairyman, I am rapidly becoming one, as a matter of education, and feel like putting in a word for the special-purpose, "screw ended" dairy cow.

As I have stated that I was neither born nor reared a dairyman, your readers may be interested to know what the circumstances were in this regard, so I will state that I was born of "down-east Yankee parentage, and reared a truck farmer and horticulturist on a forty acre farm, and my evolution into a dairyman commenced when it was discovered that the natural fertility of the soil was insufficent to raise continuous crops of vegetables and small fruits, and that it must be supplemented by fertilizers of some sort.

What should we do? Stable manure could not be got; commercial fertilizers were costly. Would they pay a profit on their cost? Of what nature should they be? These were perplexing questions for the inexperienced, and mistakes might mean bankruptcy.

With these perplexing questions uppermost in my mind, I resolved to enter the Wisconsin College of Agriculture and find, if possible, their solution.

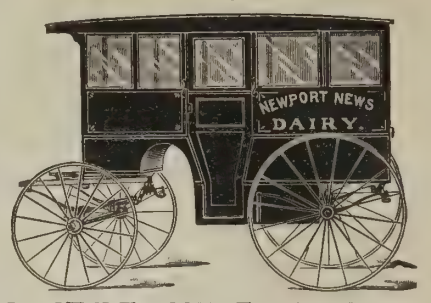
From a winter's instruction under Dr. Babcock, I learned the essential elements of fertility could often be purchased in the form of feed stuffs, cheaper than in commercial fertilizers; that they might be fed to stock, and the larger part of fertility regained in the manure; that the dairy cow was the machine that would turn the greatest amount of feeds into fertilizers in a given time, and was, therefore, the machine for us to employ in our fertilizer factory.

From a study of feeds under Prof. Henry, I learned that the foods most valuable as fertilizers were just what was needed to make a balanced ration for the cow. As a result of a winter spent in the Agricultural College, a herd was started with the first object, the manufacturing of fertilizer, and the foremost thought, the running of as much feed as possible through every machine in the outfit, and with the product of milk and butter as a secondary consideration. The herd at the start consisted of dual-purpose Shorthorns, hash-bred mongrels and one solitary triple-wedge shape, "screw-ended" grade Jersey. From experience I soon learned that the dual-purpose Short-horns were a failure as fertilizer manufacturers, for under the high pressure feeding they were soon too fat and lazy to be of much account. The proper sphere of the hash bred animals was, undoubtedly, hurdle racing, while the grade Jersey soon showed herself to be the type of machine we wanted, and, as a consequence, that type was adopted as being the one that would stand high pressure feeding, and keep right at it. So much for the screw-ended cow as a fertilizer manufacturer.

The next step of my evolution toward a dairyman, came when the year of low prices for our fruit crop compelled us to carefully consider every expenditure, lest unwise investments lead to bankruptcy; and the question arose, are these fertilizer machines paying their keep at the milk pail? Careful weighing and testing followed, which brought out the fact that while some were paying us a profit, others barely paid their board, and still others were running us in debt. This created a desire for more knowledge in regard to the cow, as a milk and butter producer, and resulted in another winter spent at the agricultural college, in studying the type, form and temperament of the special-purpose dairy cow, and since then the herd has been weeded out and improved, until the average product of the herd is over 300 pounds per cow, and several individuals are making nearly 500 pounds a year.

Careful weighing and testing still continues, and the weeding out process still goes on, for I am aiming at a herd whose average shall be close to 500 pounds a year. It will take some time, and careful selection to reach this, but I am taking advantage of the general stampede from Jerseys to Short-horns and white faced cattle, to make selections of the very best of the screw-ended type, and have purchased four registered Jerseys as foundation of a registered herd.

Some of the neighbors think I must be getting crazy to be buying Jerseys when everybody else is selling them and buying beef cattle, but I am confident that time will show that they are the ones that have lost their heads, for even with present low butter and high beef, I can get as much for a year's product from my best cows, as the beef men can get for a three-old-steer, and while I have my cow left to do the same thing over again the next year, his steer is gone and must be replaced either by purchase or by keeping an unprofitable cow. I had better say two unprofitable cows, for it is only fair to estimate that one-half the calves will be heifers.



How a farmer on high priced Wisconsin land, can get a profit out of such a deal is past my comprehension. To be sure, he will avoid some work, but my training on a forty acre farm was such that, instead of studying how to avoid work, to study how to employ the greatest amount of labor profitably on a small piece of land.

Have been a reader of the DAIRYMAN for a year and a half and consider it a great help.

W. H. HANCHETT.

MIXED PAINTS

At **WHOLESALE PRICES,** delivered **FREE** For Houses, Barns, Roofs, all colors, and save dealers profits. In use 54 yrs. Endorsed by Grange & Farmers' Alliance. Low prices will surprise you. Write for samples. O. W. Ingersoll, 267 Plymouth St., Brooklyn, N.Y.

Parted In A Dream—(New) Pronounced by critics a beautiful song. Very popular. Founded on strange incident of Cuban war. Regular price, 50c. Sent to our readers for 25 cts., post-paid, including also miniature page of DARLING LENORE and MOTHER'S DARLING YET.

Darling Lenore—(New) Is called a very catchy, pretty song with beautiful flowing melody, all in waltz time. Becoming very popular. Regular price 50 cts. Sent post-paid to our readers for 25 cts. with a miniature page of PARTED IN A DREAM and MOTHER'S DARLING YET.

Mother's Darling Yet—(New) Pronounced very pretty. Is extremely popular with singers of lullaby songs. Regular price 50 cts. Sent post-paid for 25 cts., and with it a miniature page of PARTED IN A DREAM and DARLING LENORE.

For 2 cts. I will send one miniature page of each of the three songs. Address the author,

HALBERT L. HOARD, Fort Atkinson, Wis.

Twenty-Five Dollars From Twenty-Five Cents

The Proofs Submitted in Three Sections. Referring to a Ration Formula.—An Advertisement and a Suggestion as to Skim Milk Veals.

ED. HOARD'S DAIRYMAN:—Enclosed find $1 for my renewal to the DAIRYMAN, and I wish to say I never invested a dollar that yielded me more pleasure, or profit, than will this, judging by my past short experience.

Perhaps it might interest you to know what the DAIRYMAN has done for me during the past three months. I never knew there was such a paper published until one day last February, when I saw a leaf from a sample copy at a friend's house. I immediately sent 25c for a trial subscription. That 25c has actually saved me more than $25.

Let me prove this statement. For the past two or three years I have been trying to the very best of my ability to be a good dairyman, and get something out of my cows, and that I have not entirely failed to think the following figures will show. Nevertheless, I have felt there was a fault with my grain ration, as my cows did not respond as I thought they should, although I did the best I knew. Upon reading the first number of the DAIRYMAN, I saw my need of a balanced ration and wrote you asking for one, which you kindly sent, and at once my cows began to tell me pleasant stories about it, in the milk pail and at the churn. This is saving No. 1.

Gluten feed was one of the constituents you sent me, and this I first purchased in Pittsfield, Mass., at $21 per ton. This I though rather expensive, although the results from its use were all I could ask, so I wrote to the Glucose Sugar Refining Co., of Chicago, and they sent it to me for $16.25 per ton, freight prepaid, while from Pittsfield I was obliged to pay my own freight. The feed in both cases was the very same. I saw the advertisement of the Glucose Sugar Refining Co. in the DAIRYMAN after sending my first order to Pittsfield. This I call saving No. 2.

Then I made up my mind from reading

one of the letters from a dairyman that I could do better than sell my calves for $1.00 at a few days old, as had been my practice; and so by following the advice there given, I have fattened and sold $20 00 worth of calves this spring that never had a particle of new milk after it was fit to save, and but 50 cents worth of oil meal, putting a little in each mess. This is saving No. 3.

Perhaps I ought to say, we have a U. S. separator and it has brought me as big returns almost, as has the DAIRYMAN, at least $250 over the open pans formerly used.

Now as to figures: From the 25th of May, '97, to the 20th of May, '99, (date when we bought our separator) we have made 4,863 pounds of butter from an average of nine cows, and also sold $28 worth of cream, and used cream each morning in our coffee. One of the cows has been farrow during both years, and two have been heifers with first calf. We have customers in Pittsfield for all our butter at 25 cents by the year. This would make $1,216 for butter, $28 for cream, $15 for cream used (estimated), $20 for calves fattened, and $180 for skim milk, at $10 per cow per year. Total $1,459, or $81 for each cow per year. My cows are mostly grade Jerseys.

During the next two years I hope very much to do better, and with the help of the DAIRYMAN, I think I shall.

We are now milking ten cows. One is nearly dry, one is farrow, four are heifers, and the rest came fresh last fall and during the winter. From these ten, we are now making about 12 pounds daily, or over 80 pounds a week. I hope to make them do better.

We have no silo, but the DAIRYMAN has "put it in my head", and some time I expect to build one. I have sown in a small piece, 2 acres, of Canadian peas and oats, this spring and my next improvement in dairy methods will be the purchase of a Babcock tester to try the merits of each individual cow, and weed out the boarders, if any. I feel each week, when I read my DAIRYMAN, that I am in the best of company. C. M. S.

West Lebanon, N. Y.

He is Surprised.

ED. HOARD'S DAIRYMAN:—I am a subscriber and interested reader of your paper, and would not be without it for many times the cost. I have read so much about what has been said from time to time in regard to the necessity of *testing* milk in order to detect the poor cow from the good, that I decided to try it in order to satisfy myself, and have been so surprised at the result that I doubt the correctness of the tests made, although made by a Babcock tester. I will give you the result of two of the tests. One from an ordinary cow of no particular breed, whose milk cream would never form more than a thin scum over it, and that of no body, and almost the color of common skimmed milk. This tested 3.7% fat. The other test was from a fine Jersey, a very valuable cow, and upon whose milk would raise a good heavy, thick bodied, golden cream, and whose skimmed milk to all appearance was as good as the new milk of the other cow, and this tested but 3 5% fat. Both cows were cared for alike. The first cow tested would be considered worth here about $35, and the Jersey could not be bought for $75.

If these tests can be relied on, I do not wonder that people are deceived in their cows. C. R.

Watertown, S. D.

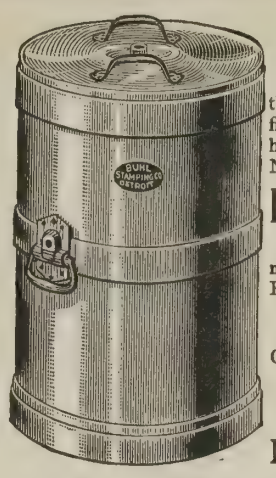
Our correspondent has received a very practical illustration of the wide difference that may exist in the milk of different cows, and also to what extent the volume of cream indicates the amount of fat present in the milk. He is only passing through the experience which many dairymen have had before, and has found that cows differ widely as to the quantity and quality of the milk produced; that neither cream nor color are always a true indication of the value of the milk, and finally that pedigree and performance do not always go together. A Babcock test has passed beyond the point where it was a luxury, and has now become a necessity to any dairyman who expects to be more than a keeper of a boarding house for cows.

It is by no means unusual, however, for a single test to prove inconclusive. Keep on with the testing, and make sure that all directions are carefully complied with, and more especially that the samples are truly representative.

The Egg Cure for Calf Scours.

ED. HOARD'S DAIRYMAN:—I may be a little late in telling the readers of HOARD'S DAIRYMAN the best remedy for calf scours, but perhaps will benefit some of them yet.

About two weeks ago, I called at a neighbor's house and my neighbor said: "I am having dreadful luck with my calves this spring. The calf from my best cow is nearly dead with scours." And sure enough he was. The poor fellow could not stand at all, and death was visible in his eyes. I gave the man a dollar for the calf, and carried him home and put five raw eggs down him, shells and all, holding his head up and pushing one egg at a time well back in his mouth and shutting his jaws together, thus breaking the egg, and held up his head until he swallowed them. In twenty-four hours I gave three more, and then two more, and that calf today is as well as any in my pasture. H. S. K.



North Ferrisburg, W. V.

Advice Wanted on Late Crop for Siloing.

ED. HOARD'S DAIRYMAN:—Would like some advice from those that have had experience, through your most valuable paper, as to what I could plant at this late day of the season to fill a silo with, this fall. As I only concluded to build a silo in the last few days, would like to have some advice through next issue. I have decided to build a stave silo and have selected the one from the DAIRYMAN of May 19, '99. A. D.

Marion, Ind.

In Wisconsin we are still planting corn and expect to raise a good crop. While we cannot speak by authority, we know no reason why an early variety of corn might not now be planted in Indiana, with reasonable assurance of success.

The Best Factory Cans.

The strong points of the Buhl Factory Cans are their great strength, heavy coating of pure tin, and fine finish. They do not rust like common cans, have no crevices inside, will not leak, and need no repairs. No other cans have the Genuine Heisey Side Handles.

Look for the Milk Can Trademark.

This Can has 3 welded, tinned, wrought-iron hoops, tinned malleable side handles, and heavy XXXX genuine Cookley K cylinders.

Capacity 15, 20, 30, 40 and 50 gallons.

Refuse imitations. We make all patterns and sizes of Milk Cans, and will gladly mail you our hand-book free.

We Make Prompt Shipment.

Mention HOARD'S DAIRYMAN.

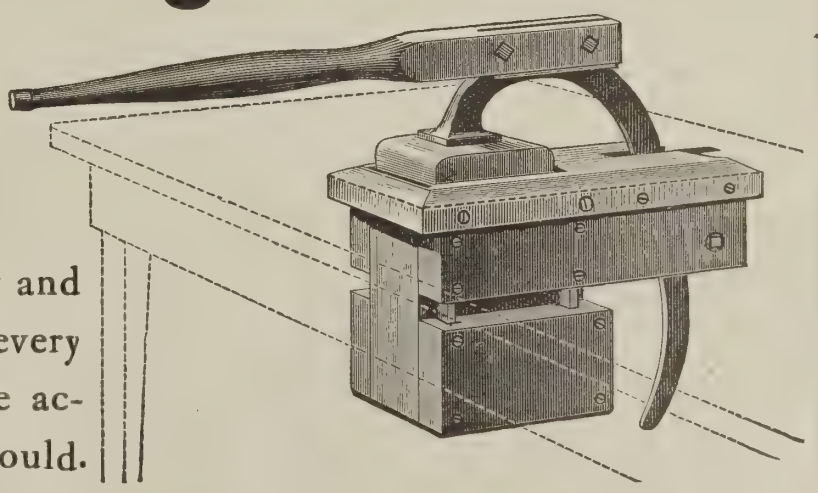
Why is a Ten Dollar Bill Always Worth Ten Dollars?—

BECAUSE THE UNITED STATES GOVERNMENT IS BEHIND IT.

Why is a Deering Binder Always Worth What You Pay for It?—

BECAUSE THE DEERING HARVESTER CO. IS BEHIND IT.

The man who owns a Deering machine knows that he has full value for his money—knows it because the Deering guaranty goes with every machine sold by them.



Deering Machines are as strong as the Deering claim, and that claim, in substance, is that Deering Grain and Grass Harvesting Machines will outclass all others in practical field performance at harvest time—that they will "clean up the crop" better than any other—that they are by all odds of lighter draft than any other—and that either in the field or on the road they are more conveniently handled than any other.

These are strong claims, but remember the Deering Harvester Company is behind them.

DEERING HARVESTER CO., - - Chicago.

We Challenge the World

To produce a better butter printer than the **LAFAYETTE.** Unequaled in **simplicity, durability** and **rapidity.** Weighs every pound of butter more accurately than scales would.

Reid's Improved Butter Shipping Box is the Best.

BALTIMORE, Md., December 9, 1898.

MR. A. H. REID,

Dear Sir :—I have used several different kinds of butter printers and have not found any to equal your "Lafayette," both for creamery work and reprinting butter. I have been using one for three years, averaging 600 lbs. of butter weekly, and it is still in fine condition and has not cost me one cent for repairs. I can see no room for improvement.

Yours truly,

G. U. MYERS.

Every Printer is guaranteed to be as represented.

Best Way of Handling Milk in Hot and Cold Weather from Weigh Can to Separator.

(Papers read at the National Buttermakers' Convention, Sioux Falls, S. D.)

Running from weigh can to receiving vat, the milk should pass through a very close strainer, cheese cloth laid inside the common vat strainer makes a very good and practicable strainer. The milk in the receiving vat should be s'irred occasionally to prevent the cream from rising to the top; from the receiving vat the milk must, if the creamery is not built on the gravity plan, be elevated into the tempering vat; the pump used for that purpose should be enameled inside and be easy to take apart to clean.

Next comes the heating of the milk, which is one of the most important parts of the buttermaker's work and the one probably paid the least attention to. While kept busy weighing milk and keeping up steam, the temperature of the milk before it enters the separator is too often neglected by the buttermaker, and allowed to go below where the separators will do clean skimming, and I believe the variation in yield of butter from one day to the other, may, as a general thing, be traced back to uneven temperature of milk while skimming. In order to obtain the best results, it is necessary for the butter maker to experiment till he ascertains at what temperature his separators will do the closest skimming. No standard can be established, as local conditions and make of separators may change it materially. When the buttermaker has found out at what temperature his machines do the best work, he should keep the milk at that degree as near as possible. He should have a thermometer placed somewhere close to the inlet of milk to the separators, and he should watch it closer than he does his steam gauge. There might be quite a difference in the temperature of two loads of milk, which, of course, would make it necessary to let on more or less steam as the circumstances might be; the falling or raising of steam in the boiler will also raise or lower the temperature of the milk, so it is absolutely necessary to watch the thermometer close in order to obtain the best results.

For heating the milk to the desired temperature, some use hot water between outside and lining of vat, some use live steam between outside and lining of vat, and others use live steam direct in the milk. When live steam is used direct in the milk, the water in the boiler should be entirely free from impurities, no boiler compound of any kind should be used, as there is but very few places where it is not necessary to be recommended, as bad flavor is very easily imparted to the butter.

Live steam between outside and lining of vat may do very well in the summer time, but in the winter when the milk requires more heating, it is simply a loss of steam; it may also cause a scorched flavor to the butter and make the milk bake on the vat inside.

There seems at present only one safe way of heating milk and that is with hot water between outside and lining of vat. When that is used there is no danger of bad flavor being imparted to the milk while heating, it will not bake to the vat, and it ensures a more even temperature, the only drawback seems to be to get a heater made substantial enough.

JOSVA MORCK.

Germania, Iowa.

That necessity is the mother of invention is proven by every advance of science, by every new invention, by every forward step in education and learning.

In no line is this fact better illustrated than in the handling of milk and its products.

Can we for a moment imagine ourselves in an age where the separator is unknown and the 632,000 cows of neighboring Iowa, have their annual product, 2,200,000,000 pounds of milk set in shallow and deep pans and make 90,000,000 pounds of butter instead of 100,000,000 pounds. Now, imagine a change when the separator is invented and the cream from this milk must be ripened in twenty-four hours instead of perhaps a week. Necessarily a new style of management must come in vogue and as a result of this we find two general lines followed, viz: that of separating at moderate temperatures and pasteurizing, each of which has many advantages.

We might consider pasteurizing as artificial and moderate temperatures as the natural method of handling milk. In the former the operator destroys the germs planted in the milk from natural sources and introduces new germs by a starter, which he believes will produce the desired flavor. This method has the advantage of securing perfect separation of the cream from the milk; also, if corresponding care is exercised in the handling of machinery and utensils, of securing the best possible degree of cleanliness, which is the one great essential to success in the creamery business. On the other hand we risk an occasional scorched flavor, possible shortage of steam, and an occasional poor starter, besides the extra labor and care.

With proper education of the patrons (which of course takes time) it would seem that the raw milk from the cow treated as nearly natural as possible, and with the least amount of labor to make a first-class product, would be the logical method, the cheapest method and therefore the best method. As a matter of fact we have two features to battle with here:—First, the great number of creameries where "cleanliness is not next to Godliness", and second, the fact that the great Danish and Scandinavin creamerymen have for a long time practiced the pasteurizing method. Nevertheless it will be sometime before we can consider pasteurizing as the best method of handling milk in the west, all things considered.

The conditions in which milk is brought to the factory in either summer or winter, are so varied, it is hard to give a treatment for all. We might give some axioms.

1. Milk should never be passed through the separator at a lower temperature than 80°.

2. Live steam should not be allowed to enter the milk except when it cannot be avoided.

3. Reject all milk that is sour, or of questionable flavor.

4. Perfect cleanliness must rule.

Follow these four and the foundation for a finished product of fine flavor will be made.

In summer the buttermaker should make his strongest effort to get the milk as early in the morning as possible before being heated too much from the sun. Be ready to weigh when the first hauler comes so as to encourage promptness by example. A receiving vat holding 400 or 500 gallons is a great help to get the milk in out of the sun. A small "Ideal" tin lined heater connected with this, holding eight or ten gallons will make the needed change in the temperature and leave the body of the milk whatever advantage it may have of lower temperature. This point will be more noticeable in case of delay by a broken belt or otherwise.

It often happens in winter that milk comes to the factory partly frozen, in such cases I have a hose to slip over a steam pipe and by the aid of this we deliver steam on the cover and neck of the can, this loosens the ice, causing it to drop off easily when shaken.

Our receiving vat is jacketed and we do part of the tempering here in winter. This lessens the flow of steam necessary in the small heater and hence decreases the coating on the inside of the heater. The "Curtis" milk heater tempers the milk in a thin layer and is claimed by some to be superior to the channel vat heater.

The operator who understands the principles underlying tempering milk will temper, not scorch it, and will raise the temperature where the fat globules are easily separated from the serum before allowing it to enter the separator, at the same time bearing in mind the fact that after treatment of the cream will be largely governed by the separating temperature.

The style of heater or fixtures are not nearly so important as to have the milk enter the separator with an even flow and temperature. Here, as in other places, it is "early start and steady pace that wins the race."

In conclusion we should urge the buttermaker to insist on having his milk delivered pure and sweet, both summer and winter.

Allow the milk to flow by gravity from the weigh can to a 300 to 600 gallon jacketed receiving vat which will protect the body of the milk, as it comes in from the heat of the sun in summer and cold in winter.

In winter temper to 65° in this vat. Let the milk flow by gravity, if possible, to whatever small heater is used. Temper here to 80° in summer and rather higher in winter. Govern the flow to the separators in this vat which transfer should also be by gravity. If direct steam is used at all use it here, but avoid entirely if possible. In all cases strain the whole milk through a good perforated tin strainer covered with cheese cloth before entering the receiving vat. He who practices this method will find it clean, economical and labor saving.

Linn Grove, Ia. GILBERT W. LOUTHAN.

The best way of handling cream from separator to finished product is a way which I have not found yet, likely never will, though I am experimenting along that road with so many others. Sometimes I think I have got ahead of the other fellows, but suddenly I get lost in the bacterial wilderness, and am glad if I find my way out again without serious loss.

Now, as I do not know the best way of handling cream from separator to finished product, I am unable to comply with our worthy secretary's request to point out this way for you, all I can do is to tell you the way which is followed at New Sweden.

When the cream runs over an open cooler to be cooled and aereated before it is emptied into the cream vat, after all or part of the cream is in the vat, a heavy starter is added to give a lighter flavor to the butter. During the day the cream is occasionally stirred and towards evening tested for acidity. I regulate by the temperature so the cream will be of the right acidity the next morning. In the morning the cream is again tested for acidity and the temperature looked after. If the cream is too cold it is warmed up in the vat by heating the water surrounding the vat. I do not use steam because it heats too quickly, thereby melting some of the cream, and this again causes hard specks in the butter. The cream is now emptied into the

churn, and if too warm, fine crushed ice is used to cool with. I want to say right here, that I do not believe in holding the cream at a low temperature before it is churned, as I have found this causes a poor yield, that is, the butter milk will test from two to four tenths of one per cent fat. This I have found to be the case every Monday morning, when the cream has been kept at a low temperature over Sunday, so as not to get over ripe.

In the winter I churn at a temperature of 55°, and in the summer at about 52°. In warm weather the temperature will rise from one to five degrees while churning, and this will again cause the butter to come soft. Then I practice to have a tub of fine crushed ice ready to put into the churn just when the butter begins to break out, this will lower the temperature down to about 50°, and the butter will then come in fine granular form. After the butter milk is drawn off, the butter is washed once, if it is in the right shape, and twice if it is a little soft. The butter is now drained a little and the salt put in by hand, evenly, over the butter, and the churn then revolved a few times before the rollers are put in gear, to get the salt well mixed with the butter. The rollers are now started and the butter worked a little, just enough to get the salt well mixed with the butter. It is now left alone until it gets hard or firm, and then worked a little again, not too much at a time. It generally takes me about two hours finishing the working, as I like to take good care here.

Want to have the salt all dissolved before I pack the butter, and do not like to have mottles or streaks, and by taking a little time and good care, we can easily get it just right. Sometimes I have to pour in the churn a dipper or two of water to get the salt all dissolved.

Now being sure of having everything as it should be, the butter is packed into tubs thoroughly soaked in brine, parchment lined, or sprinkled with salt as the trade requires it. I pack it very carefully, finish off the tub level with the edges of tub, put on a cloth circle and on top of this some wet salt, weigh each tub, and the butter is now ready, a product which will sell at highest market price or over, and probably win a gold medal or at least a prize, if there is a chance some wheres; just because I took good care and did the very best I could.

SAM HAUGDAHL.

New Sweden, Minn.

Dairywork in the Maritime Provinces.

ED. HOARD'S DAIRYMAN:—The spring was somewhat backward and very cool. Though the snow had well disappeared by the end of April, yet little was done at plowing or seeding before the first week of May. Last year the only crop the farmers of the maritime provinces could boast of was the hay crop; and that this one crop was a great one was indeed a providential blessing, and may be said to have saved the farmers. In other words, the hay crop was their salvation. As a result, dairy and other stock have an abundance of food, and even yet, after carrying the animals through a long and cold winter which includes the month of May, feed is still abundant. During the present month frosts prevailed at night up to a few nights ago.

Cows are still stabled at night and eat as much dry feed as they did in April. Owing to the continuation and severity of night frosts through this month, grass has made little growth and even the most fertile pasture fields do not yet afford sufficient nourishment *per se* to support a cow in milk.

Cows are not in the best condition this spring. As a general thing cattle did not winter well. In these parts oat straw forms a large part of the roughage during winter and last season owing to the great damage from rust, the straw was of poor quality. Another reason was the fact of the extreme shortage of the cereal and root crops which made it possible only to feed very small allowances of grain and roots. Again, millfeed, such as bran, shorts, etc., was abnormally high and is so still.

Such feed cannot be purchased by the carload in any point in the maritime provinces for less than $20 to $22 per ton, and as few farmers and dairymen can afford to buy by the carload, they must buy from retail merchants and pay at least $30 per ton. Home raised grain is this spring out of the question to feed. Oats have been selling the past month and now for 45 cents per bushel.

To give you an idea of the cost of grain feed, my team of horses are costing me 45 cents per day in grain feed alone (three pecks) Barley, another good feeding grain, is now selling for 70 cents per bushel. Corn meal sells for, in car lots, $23 per ton. So you see from the schedule of prices it is absolutely impossible for dairymen to feed grain or meal, and the cows as a consequence are thin in flesh and in very poor condition to begin the factory season.

In Prince Edward Island there were nine creameries running all winter, but owing to conditions just named, results were not so encouraging as the previous year. Three creameries are now running for cheese, but three factories that did not make butter all winter have not yet opened, but will begin operations in a few days, now. Some of the more backward ones will not begin cheese making till June 15th to 20th.

The session of Prince Edward Island local government just prorogued was fruitful of much legislation of benefit to farmers, and to dairymen in particular. A generous appropriation was made for the payment of one or more cheese inspectors, and legislation empowering the inspector or inspectors to visit each factory at stated times and see that the cheese maker acts in accordance with the instructions of the inspector. One inspector has already been appointed—a Mr. Fraser—a very competent man, it is said.

Another act passed was the incorporation and consolidation of all the dairying associations of the province with power to form a cheese board at the capital—Charlottetown. The Dominion government contributes a portion towards the payment of these inspectors. Another appropriation was for the establishment of a department of agriculture in the provincial cabinet. The new premier of the province, Hon. Mr. Farquharson, seems to be the friend of the dairymen at least.

There will be no Provincial Exhibition in Prince Edward Island this year. Our farmers and breeders will have to exhibit, as last year, at St. Johns and Halifax, and the exhibitions at the latter places promise to be fine. The New Brunswick government are giving a grant of $3,000 to the St. Johns Exhibition Association and it is expected that the city of St. Johns will give $3,000 more. Should the association obtain this $6,000, the prize list will be a liberal one.

The Nova Scotia Exhibition Association always pays bigger prizes than St. Johns does and this year the money to be distributed at Halifax will be larger than ever. At one time it was thought that Halifax, at least, if not St. Johns, would not permit competition from Prince Edward Island, as that province did not intend to return the compliment by holding an exhibition, so that Nova Scotia and New Brunswick stock might have an opportunity to compete in the Island. Last year Prince Edward Island stock took away most of the prize money from the Nova Scotians and New Brunswickers in this our ground, but Halifax and St. Johns are generous and believe in returning good for evil, and will, this year, as usual, allow competition from the Island.

Most of the Dairy Associations, which are all incorporated joint stock companies, have been purchasing feed, seeds, fertilizers, flour, etc., for their shareholders in car lots, at wholesale prices, thus saving to the consumers 25 per cent to 50 per cent on the usual retail prices.

The merchants and jobbers do not like this but they have to "grin and bear it." The eyes of the farmers are now opened to the exorbitant profits of the feed and seed merchants, and as a result, even they have been forced to lower their prices so that those not shareholders of the dairy companies are benefitted by the lower prices at which their grains can now be bought. The wheat crop being a total failure in the maritime provinces last year, almost all of the farmers were forced to import their flour from Ontario and the States. One factory during the winter, imported three carloads of flour alone for its patrons. The saving on retail prices on flour alone, was about one dollar and twenty-five cents per barrel. Another factory company imported a carload of seed oats at twenty cents per bushel less than the same was retailed by the merchants.

This method of trading for the patrons, which most of the dairy companies have taken up, has been of inestimable benefit to the people and shows up plainly that a dollar saved is a dollar earned. J. A. M.

Hermanville, P. E. I.

The "Wisconsin Idea" Spreading.

Another Guernsey Bull Calf Goes East.

ED. HOARD'S DAIRYMAN:—It would seem like an insignificant thing to record the sale of a little bull calf, but in this instance I think your readers will be interested.

The youngster is a son of Fantine 2nd 3730, and is sired by Shylock of Darlington 4579, a son of the well known cow, Nubia's Vesta 5986, with a record of 25 lbs., 8 ozs. butter in seven days and 556 lbs. butter in six months.

If the editor will bear with me for again mentioning the cow Fantine 2nd, I should like to say that since last reported she has tested 23.46 lbs. butter in seven days. Unfortunately, her best year was in 1897, at the time my barn was destroyed by lightning and it was impossible for me to continue a record of her performance, but with occasional weighings and five Babcock tests at hand, the most conservative estimate would give her credit for over 800 lbs. butter for the year. I have, however, a month's correct record of her of 1,632¼ lbs. milk, showing a 5 2% fat test, from a 7 days' composite sample. This, her last son, "Par Excellence" 5970, is now owned by Mr. H. McK. Twombly, Madison, N. J., proprietor of the well known "Florham Guernseys," of which Mr. J. L. Hope is superintendent. Mr. Twombly has already owned a son out of Fantine 2nd, for several years, in "Gold Bas's 4660," so it was not till judging by his daughters, that he was induced to pay a long price for Par Excellence.

Nashotah, Wis. CHAS SOLVESON.

More about Soja Beans.

ED HOARD'S DAIRYMAN:—In my article on Soja Beans, published in your issue of May 19th, I note an important error in giving the comparative amount of protein or nitrogen in soja beans; it should read 34 per cent instead of 3.4 per cent, as printed. Quite a difference in determining their feeding value. I also admitted in writing, that for soiling or hay, they can be planted at any time up to July 1st, though the earlier the better. Two years ago I sowed some the first week in August on rye stubble on very rich ground, and when cut seven weeks later with only one light shower to sprout them, they were waist high to me, and full of bloom. They made the richest cow hay I ever fed. I intend, this year, to sow all my oat stubble for winter cow feed.

I mention the above, for in several letters received from Tennessee to Kansas, there has been general inquiry how late they can be sown, and if they will do well on grain stubble. W. H. STODDARD.

Sons of De Kol 2d and Netherland Hengerveld head the herd. Animals of both sex and any age for sale. Write stating just what you want, HENRY STEVENS & SONS. Lacona. Oswego Co. N. Y

A GREAT RISK
For dairymen is in using as head of their herds cheap bulls. Do you know that the bull is half the herd? You may have a handsome appearing animal, but lacks in that of the most important, breeding. Only inherited dairy qualities breed on. **Valley Mead Farm** has sent out bulls to head the best herds of Holsteins in the country this spring. Thus a fact which goes to prove that the bulls bred at "Valley Mead" have no superiors in the world. A bull costing $100 is one we recommend. Start in now. Organize a company if you can not afford one alone. Address
Valley Mead Farm, Monticello, Wis.

Markham Manor Farms. Simonsville P. O., Andover, Vt.
Holstein-Friesian cattle bred from the most fashionable butter families, individually large producers, and of the most approved show form. The herd contains seven daughters of Sir Netherland Soldene Clothilde, No. 18390, H. F. H. B., the most remarkable show bull of recent years. Also large English Berkshire Swine from noted prize winning and imported stock. Write for description and prices to **J. A. THORNTON, Mgr., Simonsville, Vt.**

GUERNSEYS AND POLAND-CHINAS.
Bred from the most noted prize-winners. Calves and Pigs at bargain prices. CLAYTON C. TAYLOR, Lawton Station, Erie Co., N. Y.

GUERNSEYS FOR SALE. The increase of my herd is a few young things of both sexes, from one to eighteen months old. Prices corresponding to age and quality. **F. W. TRATT, Whitewater, Wis.**

GUERNSEY Cattle—SHETLAND PONIES.—Old Homestead Herd was Champion at O., Ill. and Ind. State Fairs, 1898, winning against well-known O., Pa., and N. J. Guernsey show herds. Over twice as much prize money as all competitors combined at above fairs. No better collection in America.
☞ Breeding Stock for Sale. Inspection invited.
L. V. AXTELL, Perry, Lake Co., O.

Riverside Guernseys.
CHAMPION HERD
AT NEW YORK STATE FAIR,
1898, in competition with the leading herds of the country, won eight firsts and sweepstakes. Young stock by **COMUS**, sire of most of the winners, for sale. Thoroughbred Poultry—the best egg-producing and general purpose varieties—Leghorns Wyandottes, Buff Ply. Rocks, Houdans. Send for circular. Stock for sale. **J. FORSYTH,**
Riverside Farm, **Owego, Tioga Co., N. Y.**

ROSENDALE
GUERNSEYS
Our herd has won first prize at the Wisconsin State Fair every year since 1894, and also won first at Minnesota State Fair and at the Trans-Mississippi Exposition in 1898. We keep only 400-lb. cows. Tuberculin tested.
GEO. C. HILL & SON, Rosendale, Wis.

"Florham" Guernseys.
First Prize Herd wherever shown, viz: New York State Fair, 1895 and 1897; Bay State Fair, 1895; Inter-State Fair, Trenton, N. J., 1895 and 1897; Madison Square Garden, 1895; New Jersey State Fair, 1897. **J. L. HOPE,**
Farm Supt., Madison, N. J.

GUERNSEYS!
84 Cows averaged 399 lbs. of Butter each in 1898.
Some Choice Young Stock For Sale.
ELLERSLIE STOCK FARM,
Rhinecliff, N. Y.

MILLWOOD FARM
Guernseys!
Guernseys of All Ages and Sexes For Sale.
Bred from Tested Dams. All animals have been tested with tuberculin and certificate of same is provided with each animal.
N. I. BOWDITCH, Framingham, Mass

AYRSHIRES Finely Bred and from the very best families. Stock for sale, bred for milk and butter qualities. Also fine herd Chester White Swine. Correspondence solicited.
FRED TSCHUDY & SON, Monroe, Wis.

Pure Untainted Milk.

How Germans Secure It.

The milk supply of the large cities in Germany has for many years been the direct concern of the municipal governments of those cities. The importance of the subject seems to have been recognized there sooner than in any other country. During his visit to Germany, Dr. D. McEachran, Chief Veterinary Inspector for the Dominion of Canada, made a careful investigation into the milk supply of the various large German cities. The largest and best equipped service he found in Berlin. Speaking about the history of the movement for a purer milk supply in that city he says:

"In 1881 the first steps were taken to provide Berlin with pure and cheap milk as well as good dairy produce, and a small building was opened for that purpose with three sale wagons. In less than two years this was found quite inadequate, the public sympathy being so fully offered to the enterprise that it became necessary to construct at once a central dairy on much larger dimensions. These buildings were gradually increased in size, and the business done became so extensive that sixteen years later, when I visited the institution, instead of three sale wagons being employed, as at first, there were one hundred and fifty-nine.

POPULARITY OF THE PLAN.

"Regarding the distribution of milk itself at the end of the first year of the enterprise nearly two million and a half litres (a litre is about three pints) were supplied to the city and in 1896, nearly twenty-seven million litres. At present, the daily quantity produced, seventy-five thousand litres, meets the needs of some forty-five thousand householders and is obtained from dairies containing in all fourteen thousand cows.

"In connection with the production of this milk, the following statistics may be of some interest: For the proper working of the apparatus necessary for the cleansing of the vessels containing the milk a daily quantity of from twelve thousand to fourteen thousand kilograms of coal is employed. The place is lighted by sixteen hundred incandescent and fifty-two arc electric lights and the power necessary is supplied by three dynamos of over a thousand amperes. In connection with the institution, there are twelve hundred workmen many of them specially employed and retained in special houses, such for example as locksmiths, tinsmiths, saddlers and other like workmen, and a special printing house has been opened in connection with the institution. About one hundred and eighty wagons and two hundred and forty horses are required to carry on the delivery work as it is at present. Not only do the wagons carry ordinary milk, but likewise whey; the best fresh milk for children, sterilized milk for children, cream, skimmed milk, butter milk, butter and various kinds of cheese, and arrangements are made whereby various kinds of fresh fruit are carried about on the same wagons.

"Having collected the milk from about one hundred and thirty different sources, there are daily brought to the dairy about seventy-five thousand litres. This having been tested as

TO ITS GOOD CONDITION,

it is then for the most part filtered through gravel, and in this way is freed from the presence of a large number of micro-organisms, and is then rapidly cooled and brought to the consumers in this form. The second portion is centrifuged, thoroughly cleansed and divided into cream and skim milk. In this way cream is reduced to two different qualities, or is used for the manufacture of butter, the yearly production of which is 250,000 kilograms. The skim milk produced is very much favored and is a cheap form of nutrition. About ten thousand litres of this are sent out daily. A third portion serves for the manufacture of cheese in which the soft cheese of the French variety occupies the most prominent place, Roquefort, Camembert, etc. Two million litres of milk are employed in this way every year. This cheese is sent throughout Germany to all the larger cities of the Empire where it is in great demand.

"What is called children's milk is obtained from farms whose cattle have the whole year been fed on dry food. The strictness with which Berlin has thus provided for unadulterated milk has had most favorable results in the quality of the milk, and the improvement of the milk in general has been most marked and has resulted in the diminution of the adulteration with water of from 14.1 per thousand in 1879 down to 3 6 per thousand in 1886, as testified to by

THE OFFICIAL INSPECTION.

"There is, undoubtedly, too, another evidence of this benefit in the diminution of mortality in children, whereas during the year of 1871 to 1880 thirty per cent of children died in the first year. In 1881 it was lowered to twenty-seven per cent, and in the present year down to 28 8 per cent. While, of course, undoubtedly, other factors have played an important part in the improvement of mortality, such as improved dwelling places, sewers, etc., nevertheless the improvement of the milk, which is almost the only nourishment for children under one year, must be recognized as having the greatest influence in this respect.

"From the small developments mentioned above up to the great increase in milk supply and analogous products there has been a further development as a result of the same enterprise. The by-products in the manufacture of cheese, butter, and such like products must be mentioned, such articles as lactic acid, lactose and various preparations of casein, all of which find a market in various parts of the country, as well as being exported for use in pharmacy, dye factories, paper, textile industries and like industries. So much has this become

AN ESSENTIAL FEATURE

of the dairy that special technical laboratories have been constructed.

"The bacteriological study of milk and its products has become so important in Berlin that it has been found necessary to establish an experimental station in which all the essential scientific questions concerning milk infection can be worked out thoroughly. Such, for example, is the effort to obtain in pure culture the various bacteria which render milk infectious. In the same place inoculation experiments upon the smaller domestic animals are carried on. Feeding experiments on both the larger and smaller domestic animals are also thoroughly carried out.

"A special laboratory for the chemical analysis of milk has likewise been created. In the year 1896 no less than 26,480 analyses were made. In consideration of these various features, the existing conditions of the milk supply are the most favorable that can possibly be obtained. Formerly the various suppliers of milk carried on a wholesale milk adulteration, and at the present time, as will be seen from the analyses, this adulteration has been

REDUCED TO A MINIMUM.

"To illustrate the importance of this analytical work, it may be interesting to note that in 1881 only 328 analyses were made; in 1891 the number had increased to over 16,000, and in 1896 nearly 27,000 analyses were made. All in all, up to end of the year 1896 there have been 202,533 analyses carried out. Such a quantity of material as this, and such a multitude of analyses is unknown in any other institution in the world. In the various departments of this work, which controls the purity of milk, there are various officers in control. The superintending of the health of all the cows concerned in the milk supply is alloted to two veterinarians, approved of by the state.

"Special savings banks, restaurants and schools are arranged in connection with the institution, as well as smaller and larger societies of one kind or another, and every care is taken for the welfare of employes when taken sick, and for the families of those who die during their term of service in this institution.

"In testimony of the excellence of this management, one sees medals of all kinds, the result of exhibitions both at home and abroad."

New York Farm and Dairy Notes.

About Silos and Ensilage.

ED. HOARD'S DAIRYMAN:—I suppose there are many farmers who read HOARD'S DAIRYMAN who will build silos this summer, and want to know which is the best silo, taking in consideration that it keeps the ensilage well, its durability, economy in building, and its appearance. Since the time my brother and I built the first silo in Delaware Co., nearly twenty years ago, there has been an evolution in silo building. The silo we built was mostly stone, and therefore an expensive one.

The perfect silo has not yet been evolved. The old square silo, double boarded horizontally on studding is too expensive, and the silage does not keep well in the corners. The stave silo has the disadvantage of shrinking too much in the summer. I have seen a good many silos, and heard a good many farmers report their success with different silos at farm institutes and other places.

From what I have learned, I think I would

LIGHTENS LABOR

Cobwebs about a house are usually the sign that the housewife has more than she can do, **the way she goes about it;** that all her time and strength are utilized in doing heavy work; that she uses soap in her cleaning. If she would only use

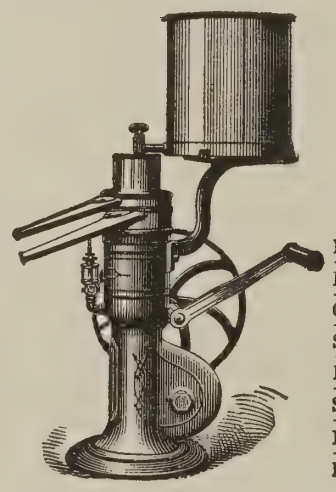
GOLD DUST Washing Powder

heavy work would be so lightened that the little things needn't be neglected. Gold Dust gives a woman time to rest, time to visit, time to read, and time to sew. It is much better and cheaper than soap for all cleaning. For greatest economy buy our large package.

THE N. K. FAIRBANK COMPANY

CHICAGO ST. LOUIS NEW YORK BOSTON

THIS PERFECTION MILK COOLER AND AERATOR



is a simple device for cooling and aerating milk. It quickly and effectually takes out all animal heat, and with it all **animal odors, odors** arising from **stables, feed, etc.** This method of treatment makes the milk keep sweet much longer. It is better for making **butter, cheese,** etc., and will stand shipment much better.

Cost But Little and Last Indefinitely.

They are made in sizes from 1 to 200 cows and will quickly pay for themselves in the increased reputation they give your product. They come very nearly taking the place of ice in warm weather. Send for illustrated catalogue and prices of **Farm and Dairy Supplies.**

American Separator Co., Box 1023, BAINBRIDGE, N. Y

agree with T. B. Terry, in advising a farmer to build a silo as follows: "I would advise the building of an 8-square silo, putting horizontal girts around, and spiking the ends where one laps over another. These take the place of hoops on the silo. Board this silo on the outside, up and down, the same as you would a barn. Board the inside with cheap lumber, and furrow out with lath, and plaster with a mortar made of Portland cement and sharp sand. Paint the outside and you will have a fine looking building. You will always find it perfectly tight and moisture from the silage cannot get to the wood work."

This kind of a silo will probably cost one-third more than the cheapest tub silo, but if one can afford the expense, I think they will be better suited with the one described. The tub silo, as it is usually left without painting or outside covering, is not very ornamental to the premises, but the octagon silo, when well built, makes a good appearance, is durable and keeps the ensilage as well as the round silo.

We built a silo on our farm that has so far given good satisfaction. Two by six studding were set in a circle on sills that were laid on a stone foundation. The studding were set one foot apart and the bottom and top securely fastened. Two courses of thin hard wood boards were bent so they could be nailed horizontally around inside the studding, and sheeting paper was put between the boards. The lumber on the farm was used, and most of the work was done by the farm help, so the cash outlay was small.

If one must economize, he can build a silo that will answer all purposes for about $1.50 per ton for the ensilage it will hold, but if one can afford the expense, he will be better satisfied with such a silo as the octagon mentioned.

Some ask me if it is practicable and profitable to feed ensilage the year around for those who have only small farms and wish to keep as many cows as possible. I know of a few farmers who, I think, are making a success of this plan, but in so intensive a system of dairying, there is a good deal of hard labor involved. If many cows were kept the work of handling so much fodder and manure all the year around, would be considerable.

On a few acres, and with a few cows, it may be the best plan, but I would want sufficient land to practice a three or four year rotation of clover, corn, wheat or oats, to seed to clover with, and perhaps oats and peas would come in the rotation. The work is better divided during the season. The growing clover would benefit the soil, and the clover hay would help to balance the ensilage, so that less grain need be purchased.

Clover and corn are the crops with which to build up a farm, so it will carry a large stock, and good clover hay and good ensilage are the most economical rations for feeding the dairy cow. Very much depends on the quality of the ensilage. Corn that grows thick together, and is immature and watery, makes poor ensilage, while corn that is so thinly planted that it ears well, and is cut when the ears are in the glazing stage, cooks in the silo and keeps sweet.

THE CULTIVATION OF THE ENSILAGE CORN.

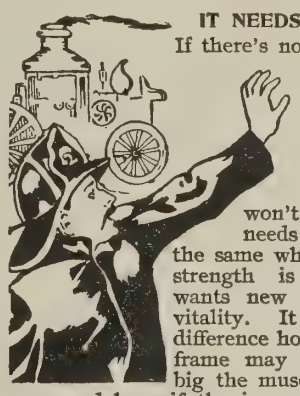
The objects we should work for in the cultivation of the corn, is to conserve moisture, aerate the soil, make its plant food more available, and prevent weeds from growing. We want to cultivate as cheaply as possible, and so reduce the cost of growing the crop. To do this we must have suitable tools for doing all the work by horse power. We can hardly afford to use the hand hoe in the corn field.

The tools needed are a weeder and horse cultivator. The weeder, if used soon after the corn is planted, and until the corn is two or three inches high, will destroy the weeds just as they are starting to grow, and save much work in the after cultivation. When the corn gets up about four inches, is the time to use the horse cultivator.

If only a few acres of corn are grown, one can do the work very well with the one horse cultivator, but for large fields, the two horse cultivator is needed. At this time the roots of the corn have not made much growth, and I would cultivate deeply to thoroughly stir up, and aerate the soil. I would cultivate deeply for a few days, and use the weeder in connection with the cultivator, to destroy the weeds in the drills where the cultivator teeth do not go.

When the corn has grown six or eight inches high, stop the deep cultivation, and do not cultivate over two inches deep. By this time the corn roots will be growing out between the rows, and we do not wish to cut them off. Of course, one must adapt the cultivation to circumstances. Less cultivation will be done during wet weather, but when the soil dries sufficiently, start the cultivator and break the crust on the surface.

The farmer who uses the one horse cultivator, can regulate the depth by the wheel in front, and a board attached to the rear. Such a board is very useful in dry weather. A board about 15 inches wide is about right, and with some bolts or wires one can fasten it to the rear of the cultivator. W. J.



Delaware Co., N. Y.

The Iodide of Potassium Treatment for Milk Fever.

ED. HOARD'S DAIRYMAN:—I have read with much interest an article on page 254, current volume, about milk fever, by S. B. Nelson, of Washington state. I don't understand the use of the apparatus. What is the shear-like thing for? I see reference letters about it, but there it stops. Give me, if you can, size of tubing, size of piece to enter teat, and how to inject it? Or, would a rubber syringe do also if nozzle was small enough? If this treatment is as successful as claimed, would it be worth the while of every dairyman to fix up to have it and the use of it understood? Or, can the apparatus be bought complete? I don't suppose that the fluid is intended to run into the teat by gravity? C. H.

Bardstown Junction, Ky.

The article referred to is simply a small spring clamp for compressing the rubber tube so that the solution will not flow out before it is wanted. Use quarter inch rubber tubing and use a milk tube for the end nozzle. Hang the receiver for holding the solution, 3 to 4 feet above the cow's back to give the necessary force to the solution and it will run into the teat by gravity. There is no apparatus in the market, but any apothecary can fix one for you.

IT NEEDS STEAM.

If there's no steam in a fire-engine it won't do its work. Heavier metal or larger wheels won't help it. It needs *steam*. It's the same when a man's strength is gone, he wants new life—fresh vitality. It makes no difference how large his frame may be or how big the muscles on his arms and legs; if the inner power and force of life is lacking he can't do his work; he is practically a sick man. You can't make him well by feeding him with oily emulsions. There's no use in flabby fat. His proper weight will come after he gets well. The first thing he needs is strength, force, *steam*.

"About a year ago," says Mr. John Brooks, of Boylston, Mass., "I was taken with a bad cold which settled on my lungs. The doctors said I was in consumption and could not get well. I took emulsion of cod liver oil and it did me no good. After taking it four months I heard of Dr. Pierce's Golden Medical Discovery, and wrote to him for advice. I have taken this medicine and it saved my life. I felt so sick when I wrote to him I thought I would not live the winter through.

"In the morning I would raise an awful lot and spit all the time, with pains in my chest all the time. My bowels would not move more than once or twice a week; my strength was nearly all gone; I could not do a whole day's work. Now my bowels are regular every day, and I feel no more pains in my chest. I feel a great deal stronger. I am working hard every day, driving a team in the woods, and I owe my thanks to Dr. Pierce's Golden Medical Discovery. I know it saved my life. I cannot praise it enough. I am proud to tell my friends what cured me."

The way this great remedy acts in bronchial and lung diseases is more fully described in Dr. Pierce's great 1000-page Common Sense Medical Adviser, sent FREE for 21 one-cent stamps to pay the cost of mailing *only*. Address Dr. R. V. Pierce, 663 Main Street, Buffalo, N. Y. He is always ready to give free advice by mail.

The One Successful Color

IT gives entire satisfaction and is the only color that buttermakers should use. It is the one color found in over ninety per cent of the creameries of the country. Butter containing Wells, Richardson & Co.'s Color has the highest standing in the markets. . . .

O. DOUGLASS BUTTER CULTURE.

ST. GEORGE, MINN., Feb. 20, '99. O. Douglass Butter Culture Co., 81 Austin St., Charlestown, Mass Dear Sirs:—In the Genesee Salt contest I scored 97½; at the State Fair, Minnesota, I scored 95½; at Sioux Falls Convention I scored 95; being a money winner at each. I used your culture in all of the above. C. H. CLEVELAND, St. George, Minn.

O. DOUGLASS BUTTER CULTURE CO., 81 Austin St., Charlestown, Mass.

A Lawyer Returns to the Farm.

His Methods and Results.

The following address was delivered before the State Agricultural Association of Iowa at its winter meeting in Des Moines, by Judge Hubbard, of Cedar Rapids in that state, and is replete with sound doctrine. Forty-five years of training in a law office and trial courts seems to have qualified Judge Hubbard to sift and weigh evidence pretty accurately and to reach wise conclusions. Experience is a good thing, but personal experience at best is limited, and he is the wise farmer and dairyman who is willing to be taught by the experience of others. This is what the Judge said:

Having been raised on a farm, it occured to me that, after practicing law for forty-five years, I should be very glad to get back to farming again. So, fifteen years ago, I purchased a farm of 340 acres, mostly within the limits of the city of Cedar Rapids. It was timber land mostiy, and I have cleared it up and grubbed out the stumps. The soil is a rich, strong clay, with a very slight sprinkling of sand, just enough to make it quick, but not enough to cause it to wash. I raised fast horses for a number of years, but the prices became too low, and, two years ago, I started a dairy of seventy five cows, and have the finest cow barns and milk plant in the state. I conceived the idea that corn and corn fodder enough could be raised on forty acres of ground to keep one hundred cows for six months in the year. This year is the first experiment. I had thirty-six acres of corn, which will average about sixty bushels to the acre, and would have averaged one hundred bushels only for the wind blowing it down, and for the hot southwester for ten days in July, just as it was earing. I had six acres that was planted later and on lower ground, which yielded something over one hundred bushels to the acre of elegant corn, and about four and a half tons of dry corn stalks to the acre. I plowed my ground six inches deep, and did not begin plowing until about the first of May. As soon as plowed, I dragged it twice over thoroughly. I planted thirty acres and finished on the 25th of May, and, on the 28th of May planted the last six acres. As soon as the corn was planted I commenced dragging it, turning the teeth back, and dragged t both ways twice before the corn came up. When the corn came up, my corn field looked like a garden ready for sowing the smallest seeds. Not a weed had started. The continual dragging wholly prevented.

As soon as the corn showed in the rows, I dragged it with the rows, keeping the horses off the corn. My corn was planted three feet eight inches apart one way, and averaged about twenty inches the other way, with two or three kernels in the hill. The stand was perfect. By the time the corn was thoroughly dragged the fifth and last time, the cultivators went in with the shovels turned to throw the ground from the corn. Great care was taken not to cover up any corn. Two teams did the work, and time was taken to do it carefully and well. In two or three days the cultivators were started with the shovels turned to throw a little dirt towards the corn. When this was completed it was found that some weeds had started and with sharp hoes they were cut out. About the 25th of June, the cultivators were put in for the third and last time, and the corn well hilled up and laid away about the 28th of June. It then stood nearly breast high. Early in July, and just as the corn had commenced to ear, a heavy wind storm bent it over very considerably, but it straightened up fairly well. Then came a hot, southwest wind with no rains for nearly ten days, and the thirty acre field planted first literally halted and did nothing. Finally a rain came and it commenced to ear, but part of my corn on the highest ground failed to ear satisfactory.

It was cut with a McCormick twine binder and shocked in about sixteen bundles each. It cured nicely, and the fodder is of a very superior quality. When sufficiently dried out, it was hauled off the field and stacked about four shocks in the stack, and is keeping well. Early in December I shelled the corn and shredded the corn stalks with the thresher, and have as fine fodder for cows as can be made. The cows eat, practically, the whole of it. I feed ground corn meal mixed, part of the time with bran, part of the time with flax seed meal, and part of the time with oat meal mill product. We are now milking fifty-five cows, and get an average of eight quarts to the cow a day, which we think good for this time of year.

The corn fodder from these thirty-six acres was more than double the amount which can be raised by planting the corn three feet, eight inches each way. Cutting out the weeds with hoes, where the corn was drilled, required from five to six men two or three days, which did not cost much where the men were required for the dairy. My corn averaged about ten feet high. It was literally a wilderness of corn. This coming year I expect to raise fifty acres and get corn fodder enough to take care of 125 head of stock. I have no doubt that some mammoth clover and millet are desirable for changes of feed.

My cow barn is 170 feet long and forty feet wide; nine feet in the clear, ship-lap on the inside, thoroughly paved with paving brick, with gutters of Portland cement for the droppings, and two 100-barrel cisterns just outside the barn, with Bell traps and sewerage pipes to take off the liquid manure, which is drawn off and sprinkled on the land with a sprinkler. In the center of the barn is a driveway and feedway twelve feet wide through the entire barn, with a cross drive in the center, and four large feed rooms. Corn fodder is stored in the mow above the cows. Next to the barn is the work room, thirty feet square, with a gasoline engine of five-horse power, which grinds the feed and runs the milk plant, including the pasteurizing plant, separators, etc. The milk room is sixteen by forty-six feet with cold storage room, steam plant for sterilizing milk bottles, pails, cans, etc.

It is two miles from the center of town to the center of my farm where my buildings are. We run two milk wagons in the city, disposing of about 440 to 450 quarts of milk and other products from it daily. I have about thirty head of horses and one hundred head of cows and young heifers, from which we haul out about five loads of manure every morning and distribute it on the corn ground. Last year fifty acres of timothy meadow were well sprinkled with the liquid manure from the vats and it produced about 150 tons of the finest timothy hay. It is safe to say that my land is being improved in value at least $3 per acre per year by reason of the increased capacity for production from fertilizing.

The state of Iowa ought to produce five hundred million bushels of corn per year, and will when it is properly farmed. And the corn fodder alone should be sufficient to to keep five million head of cattle during the winter season.

A McCormick twine binder with three horses and one man will cut and bind from six to eight acres of corn per day, and one man more will shock it. If we count three tons of dry corn stalks per acre to the average crop of corn, this will make eighteen to twenty-four tons which is equivalent to the same weight of timothy hay in nutrition. And, for succulent qualities, for milk cows, is much superior to timothy hay.

There has been much said about the cost of preserving corn fodder, but, with the twine binder and the thresher, the cost is very little more than that of cutting and storing an equivalent number of tons of timothy hay.

There is no other 55,000 square miles of contiguous territory on the face of the earth that will produce as much subsistence as the state of Iowa. It ought to, and will some day, furnish subsistence for ten millions of people. There is no business which requires more skill and painstaking than good farming. The great waste of corn fodder which we see every year, must and will be stopped before many years. There is no other one thing where there is so much waste in farming as in the failure to save corn fodder. I do not know much about protein, carbohydrates, and other scientific qualities of feed, but I do know that cattle and horses kept on corn fodder in the winter, come out looking better in the spring than those kept on any other feed. Of course, this on condition that the corn fodder is properly secured, cured and economically fed.

In March I expect to sprinkle thirty or forty acres of my pasture from my liquid manure tanks, and hope for good results in early and strong pasture.

The large increase of the exportation of corn for human food is making the two billion bushels of corn raised in the United States scarce and high. Before the next corn crop matures, corn will probably be 35 to 40 cents per bushel. Everything points to the necessity for the state of Iowa to increase its corn output. Other grains are useful, but corn is surely king in Iowa. Let us raise corn.

Treatment of Hog Cholera.

Care and Medication.

The latest words on this subject are from Dr. D. E. Salmon, Chief of the Bureau of Animal Industry, Washington, D. C., and coming from such a source, are worthy of the most careful consideration. Those in communities now free from the disease, no less than those where the disease prevails, should give heed to the suggestions which follow, and carefully preserve the prescription for use in case of necessity.

In matters of this kind it is the part of prudence to be prepared to meet the enemy at its first approach, and not be obliged to wait weeks or even days for the answer to an inquiry:

Can hog cholera be cured, and, if so, what remedy will restore the diseased animals to health?

With all diseases of this class, prevention is cheaper and in every way more satisfactory than medical treatment. The aim, therefore, should be to prevent the spread of these infectious diseases; but in spite of all preventive measures many herds will be infected, and it is therefore perfectly legitimate to ask and answer all questions as to the proper medical treatment. A remedy which will cure every case is not to be expected, for there has never been discovered a remedy for any of the infectious diseases of man or animal that would cure every individual attacked. Some forms of these diseases are so violent and rapid that there is not time for the most active remedy to produce a beneficial effect.

In many outbreaks the type of the malady is less virulent, and there is time to treat the animals after they are sick, and also the whole herd afrer some of its members are diseased. For a long time the writer was doubtful if any remedy or combination of remedies could be made which would produce any marked effect. The experiments, however, indicate that treatment, if properly applied, may be successful.

The most efficacious formula which has been tried, is the following:

Wood charcoal	1 lb.
Sulphur	1 lb.
Sodium chloride (common salt)	2 lbs
Sodium bicarbonate	2 lbs.
Sodium hyposulphite	2 lbs.
Sodium sulphate	1 lb.
Antimony sulphide (black antimony)	1 lb.

These ingredients should be pulverized and thoroughly mixed. The dose of this mixture is a large tablespoonful for each 200 pounds weight of hogs to be treated, and it should be given only once a day.

When hogs are affected with these diseases they should not be fed on corn alone, but have, at least once a day, soft feed made by mixing bran and middlings, or middlings and corn meal, or ground oats and corn, or crushed wheat, with hot water, and then stirring into this the proper quantity of medicine. Hogs are fond of this mixture; it increases their appetite, and having once tasted it, will eat food containing it when nothing else would tempt them.

Animals that are too sick to eat should be drenched with the medicine shaken up with water. Great care should be exercised in drenching hogs or they will be suffocated. Do not turn the hog on its back to drench it, but pull the cheek away from the teeth so as to form a pouch into which the medicine may be poured. It will flow into the mouth, and when the hog finds out what it is he will stop squealing and swallow. An easy method is to cut off the toe of an old shoe, insert the cut end in the pig's mouth and pour the medicine into the shoe.

In many of our experiments hogs which were so sick they would eat nothing have commenced to eat soon after getting a dose of the remedy, and have steadily improved until they appeared perfectly well. This medicine may also be used as a preventive of these diseases and for this purpose should be put in the feed of the whole herd. Care must be taken to see that each animal receives its proper share.

Success or failure with this remedy depends largely upon the manner in which it is used. If it is improperly administered, or the hogs left out in cold storms, and compelled to remain day and night in mud 6 inches or a foot deep, through which they are obliged to search to find an ear of corn in order to get something to eat, the farmer might as well save his money and let his hogs die, as nothing will have much effect under such conditions. If, on the other hand, the sick animals can be made reasonably comfortable, and given soft, easily digested food to eat, the medicine of which we have just given the formula, may be used with confidence that it will give as good results as any available remedy.

In treating hogs for these diseases, it must not be forgotten that in nearly all cases there is more or less inflammation of the internal organs, and particularly of the stomach and intestines. To treat such diseases successfully the animals should be kept dry and comfortable, and where drafts of air will not blow upon them. The food must be such as can be digested by the irritated and inflamed organs which are charged with this function.

When hogs are first found to be affected with disease, the lots or pens where they have been confined should be disinfected by dusting plentifully with dry, air-slaked lime, or by sprinkling with a twenty-five per cent solution of crude carbolic acid. The animals should then all be moved to new quarters. If possible the sick and apparently well should be separated before they are moved and then put into different lots. This is not essential, but it is an aid to the treatment. The hog should be kept in dry lots or pens where there is no mud and above all no stagnant water. It is well to keep these lots disinfected by the free use of air-slaked lime or carbolic acid.

During this treatment the hogs gain a marked degree of immunity. This is no doubt the result of attacks of the disease from which they recover. This recovery is in spite of the continued infection of the premises, and even though the hogs which have passed through the outbreak are apparently well and thriving, new hogs added to the herd are liable to be attacked. For this reason five or six months should be allowed to pass before any new hogs are purchased and brought to the premises or before any are sold to be put among other lots of hogs. Pigs born under such conditions are sometimes able to resist the infection, while in other cases they may suffer severely or die.

If any hogs die during the outbreak their carcasses should be immediately burned and the places where they have lain on the ground over which they have been dragged should be disinfected with carbolic acid or lime according to the method already mentioned.

The Ethics of the Oleo Color Question.

The oleomargarine men are more skillful at making an argument than they are at making wholesome food. The real point in the vigorous attack against them, has been the effort to prevent their coloring oleo in imitation of butter. They reply that they have just as much right to use the color, as the butter maker has. But this is not true. When the butter maker uses color, his object is to please the eye of the customer, just as he pleases his taste, when a delicate flavor is developed. The butter maker has a right to cater to the sense of taste. On the other hand, the oleo maker, when he uses color, does it with the intention of deceiving the eye and not of pleasing it, and therein he practices deception, and relies on that deception for aid in selling oleo for the price of butter. He knows full well that the consumer would discover the quality of the food, if he were not deceived by its color.

Motive determines the quality of an action. If the motive is bad, the action results in evil. The motive in making oleo is bad, it is intended to deceive. It does deceive. Very few people would buy uncolored lard and tallow as a substitute for butter. Nobody would pay the price of butter for uncolored tallow. The coloring matter in common use in oleo is a rank poison. Oleomargarine is conceived in sin, and brought forth in iniquity. It is a child of the devil and bred in line. It is a fraud and a cheat, and so are those who make it and sell it. The sooner it is taxed out of existence the better for the public good.—*Dairy and Creamery.*

A Canadian dairyman, who has been making a close survey, says:

"Not one farmer in one hundred who keeps cows has accurate knowledge of their value individually. Not one in the same number can certainly say which is his best cow, which his second best, and so on down, even in a herd of half a dozen. Where is he who knows whether or not his herd is profitable, much less the individuals of the herd? These seem strong sayings, but this is no time nor subject for platitudes."

For Sale! CREAMERY located at Macon, Mo. Fully equipped and ready for use. Has four skimming stations in connection, all fully equipped and ready for use. Has been successfully operated for two years. BIG BARGAIN can be had. For particulars address **HUDSON-GARY LAND CO**, Agts. for Trustee, Macon, Mo.

8000 BICYCLES Overstock: Must Be Closed Out. STANDARD '98 MODELS, guaranteed, $9.75 to $16. Shopworn & second hand wheels, good as new, $3 to $10; Great factory clearing sale. We ship to anyone on approval & trial without a cent in advance. **EARN a BICYCLE** by helping us advertise our superb line of '99 models. We give one Rider Agent in each town **FREE USE** of sample wheel to introduce them. Write at once for our special offer. MEADE BICYCLE CO., 290 Ave. S., Chicago. Ill.

Killing Liveforever.

ED. HOARD'S DAIRYMAN:—In reply to W. W. B., on page 288, to exterminate liveforever, turn it under, plowing it deep enough to cover all, leaving none on surface, just before blossom time. Float and harrow to exclude all air. Like purslane, it will rot very quick under ground. Will be in time for some late crop, as turnips, etc.

Pinfield, Mich. E. J. S.

The Weight of Milk.

Milk is a deceptive article so far as weight is concerned. In a herd of 50 cows samples of milk can be taken from individual animals that show interesting conditions when placed upon the scales. The milk from one cow will weigh two pounds to one and one-half quarts, while her nearest neighbor produces milk which weighs two pounds to one and one-half pints. It does not seem to make much difference what the breed is or how much milk they produce. The milk is a little lighter in summer than in winter. It is hardly possible to find a dozen cows whose milk will weigh alike, but when mixed, if there are not too many in the lot that give very heavy milk, it will weigh out two lbs. to a good full quart every time. The family who buys from a man who keeps but one cow is liable to get a little more or quite a little less of weight when buying a quart than as though the quart was taken from the mixed milk of a dozen cows.—*Orange Judd Farmer.*

The above has been widely copied, without any one, apparently, taking the trouble to verify the figures. Yet it is absurd on the face of it.

The average weight of a quart of milk is 2.15 pounds; that of a quart of water, 2.087 pounds.

Milk is always heavier than water—the range in specific gravity being from 1.029 to 1.035. This corresponds to a difference of .013 pounds or a little over .2 of an ounce per quart.

The figures above quoted would call for a variation in weight of a quart of milk of 1.33 pounds. According to the first figures given, a quart of milk would weigh 1.33 lbs per quart, and according to second figures 2.66 pounds per quart—a manifest absurdity.

Possibilities in the Orient.

Dr. S. A. Knapp, who was sent by the U. S. Department of Agriculture to Japan, China and the Philippines as an agricultural explorer, has reported to Secretary Wilson the results of his explorations.

He reports that he arrived in Japan, September 29th, 1898, and at once entered into investigation of the rice industry. The result was that ten tons of the best seed rice was bought and sent to the department for distribution.

Among valuable plants selected was a forage plant of great promise. This is "hagi" (Lespedeza bicolor). Its assumed superiority is that it is more easily set in land than alfalfa, more tenacious, with equal nutritive value.

Incidentally, the Japanese system of agriculture is described. The report says that the limited amount of arable land in Japan, about one-eighth of the total, makes it necessary to conserve and stimulate all the productive energies of the soil available. Hence, the field crops are all managed on garden methods. The seed of all the wheat, rice, rye and barley produced is first sown in highly fertilized beds, and when the plant is of a sufficient size it is transplanted into the fields. He concludes that all fear of competition from Japan along agricultural lines may be dismissed. On the contrary, it must become a large consumer of farm products drawn from the United States.

The diffusion of knowledge and the introduction of new industries in Japan have had the effect of more than doubling the cost of labor in the last ten years and, in proportion, of stimulating consumption by the common people. Future progress must be mainly made in the direction of manufactures. In such event the food for the operatives, the cotton and other fiber material for the fabrics, the lumber and iron for the construction of the factories and much of the machinery will be drawn from the United States. This will tend to stimulate the prices of our farm products. The same general facts hold good for China. The opening of the Orient to commerce will act most beneficently upon our agricultural industries.

The principal agricultural products imported into Japan are wheat, flour, sugar, cotton, butter, cheese and meat. The annual value of these articles is at present between twenty-four and twenty-five million dollars in gold. Under favorable treaty regulations Japan will import from the United States nearly all her flour, butter, cheese and meat, three-fourths of the raw cotton required, and from the Philippines nearly their entire surplus output of sugar.

The butter and cheese market will be of comparatively slow growth in Japan, but will steadily improve if properly fostered. The matters of most vital importance to the butter trade are the following: First, shipment of first quality butter for table use; second, small air-tight packages with official stamp on same, denoting inspection and certifying to trade; third, cold storage on ocean transportation at reasonable rates for small quantities; fourth, the establishment of cold storage in the leading cities of the Empire. Cheese rests upon a different basis and can largely be left to the ordinary course of trade. The conditions of the butter and cheese trade in Shanghai and Hongkong, China, are almost identical with those of Japan, except that at Hongkong, Australian butter is a strong competitor by reason of low freight rates. In the interior of China considerable French butter is sold. Many claim that it resists heat better than the American product. The same suggestions for the improvement of trade in Japan are applicable to China.

The great area, the large per cent of fertile lands, and the enormous population of China, stagger the observer on the threshold of investigation. Here, however, as in Japan, radical changes in agricultural methods or products must be made very slowly, if at all, because the food supply cannot be materially reduced or even changed with safety. Large areas devoted to fiber plants for the promotion of manufactures would be a dangerous invasion of the acres necessary for the food supply and must be speedily followed by importations from the United States. Doctor Knapp reports that he was deeply impressed by the alert, industrious and frugal character of the Chinese.

From China he proceeded to the Philippines, and there took up the same line of investigations pursued in Japan.—*Western Creamery.*

CONCERNING OUR ADVERTISERS.

The Deering Ideal Mower, made in Chicago, affords an interesting study in advanced machines, and is as perfect a machince as brain, brawn and money can build. It is furnished throughout with Deering Roller and Ball Bearings. The "Ideal" has a very wide truck and high wheels, insuring great stability and ample traction. Its gears are light, strong and reliable. In this machine the amount of lost motion is so slight that the instant one of the mower wheels starts it communicates power to the crank shaft and knife, thus making it possible to start in heavy grass without backing. The knife may be removed in fifteen seconds, simply by raising a latch. It is the only mower on the market equipped with ball bearings of the bicycle pattern.

JUSTICE.

A Pair of Scales—Justice is always represented with a pair of scales in her hand This is because the scales not only suggest a fair division, but because they present a means for checking extravagance, watching frauds and stopping leaks. Stop trying to farm by guess. Be accurate and know what you are doing. Look over the catalogue of the Osgood Scale Co., 91 Central Street, Birmingham. N Y., and see what scale you need. These men ship scales on trial.

SPRING GROVE DAIRY, Pa., Aug. 3, 1897.
THE CRESCENT MFG. Co.,
Philadelphia, Pa.

GENTLEMEN:—I tried your "Tough on Flies" last year and found it to pay. You will find enclosed, post office order for $1.50. Please send me 1 gallon "Tough on Flies".

Respectfuly yours, MCCLELLAN SWARTZ.

VETERINARY.

Queries in this department answered by WM. HORNE, M. D. V. S., Janesville, Wis.

COW PHYSIC—Three-fourths to 1¼ pounds Epsom Salts (according to age and size of animals) and two ounces of best ground ginger. Pour over this three pints of boiling water. When at 105° F., give gradually as one dose.

SIGNS FOR BEING WITH CALF.

I have a Jersey cow which was three years old last August, at which time she dropped her second calf. On October 3, she was served to bull, and on October 22 she again bawled, but this time was not taken to the bull, and since that date she has neither bawled or shown any signs of heat. Do you think she is with calf, and as a rule do cows ever bawl after having caught? On what date will this cow come in? If she was not in calf, would she bawl and show other indications of heat every three weeks? What would the result be if cow was allowed to dry up and then proved not to be with calf?

Detroit, Mich. I. G. Mc C.

ANSWER.

Cows do all sorts of things. Some bawl, but not often when first in calf. I can't say, but hope and think she is in calf. If she had not stuck, I think she would have bawled and shown other signs of being in heat. She would simply be dry until next calving. This would be all likely to occur.

TUMOR OR WART.

I have a cow with a small lump on point of left shoulder about the size of a hulled hickory nut and five or six others ranging in size from above to size of a pea. She is in excellent condition and is giving a big flow of milk. C. W. S.

Williamsburg, Iowa.

ANSWER.

I believe I would let the tumor or wart alone for a while, and observe, exactly, the condition in a few weeks. If they are dormant then, and cause no inconvenience, still let them alone. Report in a month if there is any change in size or number, and then I will advise you what best to do.

BLOODY MILK.

I have a good grade Jersey that seems to have one tender quarter. Every little exposure to cold, it will give bloody milk and show a good deal of inflammation. Have two of her heifers that seem to be the same way. I think they were both overfed with grain contrary to directions. Do you think that was the cause, or do they inherit it from their mother? A. R. T.

San Bernadino, Cal.

ANSWER.

Yes, overfeeding, in anything, man or beast, is the source whence come many ailments, and if not the direct cause of the trouble named, is surely quite a factor in causing them. There is always, when a number of similar ailments occur in a herd, a general cause. Hereditary predisposition may be largely your cause. Reduce condition. Don't ever over feed; give two teaspoonfuls of nitre each morning, for quite a long time if needed. Physicking will be your chief reliever always.

LUMP ON JAW.

I have a grade Jersey heifer about six months old that has a lump or swelling between her lower jaw bones, just under the mouth. What is the cause of it, and what shall I do for her? She is in fine condition. I had a cow the same way this spring. I have often seen stock in a bad condition affected this way, and, as a rule, die. My heifer has a fine appetite. J. H. P.

St. Francisville, La.

ANSWER.

Impossible to state the cause. It may be of a spontaneous origin, or it may be, and likely is, from some accidental bruise or other hurt. It may be much more serious in its nature, and I seriously recommend a personal examination, so as to determine the nature of the swelling. All such swellings are of a suspicious nature, always.

TUMORS.

What is the cause and cure of what seems a tumor, both on briskets of a mare or cow; large as two fists. Have lanced; a watery and bloody fluid exuded, but swelling on cow increased, while on mare somewhat decreased, but very hard. Have stopped milking cow. Both animals seem healthy.

Mission Hill, S. D. G. L. G.

ANSWER.

Lancing by laymen is very wrong. If a tumor be ripe, lancing is the proper act. If not ripe, it is always wrong, and in every case makes the thing worse. The tumors should have been poulticed or severely blistered and brought to a head and then lanced. Thus the tumors would have been removed permanently, almost certain. After your malpractice they will likely enlarge and remain. You should have availed yourself of your privilege in the DAIRYMAN at the beginning. Impossible for me to name the original cause. There are many, chiefly injuries of some kind.

ANTIABORSIO.

WILL PREVENT ABORTION in cows and cure scours in calves. One gallon will treat twenty cows three months.

Our Specific No. 1: Absolutely prevents Hog Cholera and Swine Plague, and will cure 90 per cent. of sick hogs

Our Specific No. 2: Prevents and cures Roup and Gapes, and kills Vermin on Poultry, also kills Ticks on Sheep. These are established facts, not experiments.

Our remedies are liquid germicides applied by sprinkling in closed stables and pens. Cures by inhaling fumes which destroy the germs of disease.

Send for free booklet and testimonials.

Animal Germicide Co., 319 Washington St., N. Y.

KIDNEY TROUBLE Is a deceptive disease—thousands have it and don't know it If you want quick results you can make no mistake by using Dr. Kilmer's Swamp-Root, the great kidney remedy. At druggists in fifty cent and dollar sizes. Sample bottle by mail free also pamphlet telling you how to find out if you have kidney trouble.

Address, Dr. Kilmer & Co., Binghamton, N. Y.

CANCER cured at home. Send four cents, stamps. 80 page book, illustrated Dr. J. B. HARRIS, 2226 Kemper Lane, Walnut Hills Cincinnati, O.

Milk Fever CURED by the Schmidt Treatment 90% of cures in first 412 cases. Simple and effective. Two complete treatments packed ready for instant use. For sale only by GARDINER BROS., 220 E. Preston Street, Baltimore, Md.

ROBERTS' ANTI-ABORTION SERUM

Hypodermatically administered, is a POSITIVE CURE for abortion in cows. SWORN testimonials furnished on application. Dr. D. ROBERTS, Veterinary Surgeon, Address, Waukesha, Wis.

Trade Mark

LUMP JAW

Easily and thoroughly cured. New, common-sense method, not expensive. No cure, no pay. FREE. A practical, illustrated treatise on the absolute cure of Lump Jaw, free to readers of this paper.

Fleming Bros., chemists, Union Stock Yards, Chicago, Ill.

ABORTION!

Retention of Placenta and Failure to Breed.

H. W. KELLOGG'S experience with and positive cure for these diseases in cows. Send for circulars. Address all communications to H. W. KELLOGG COMPANY, Ripon, Wis.

CONTOOCOOK, N. H., March 6, '99.

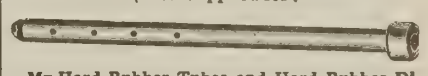
H. W. KELLOGG CO.,

Gentlemen:—About 18 months ago I began using your Abortion Cure. My cows were losing their calves one after another. After the medicine had time to take effect I had no more trouble. The cows ate it readily and I believe it a preventive.

Yours very truly,
G. A. CURTICE.

Dr. Horne's Anti-Abortient

Prevents Abortion and cures Nymphomania—failure to breed; also Emmenagogue Powders for cows failing to come in heat. Both powders are the result of long practical experience and study and may be given in a little moist feed. 5 oz. $1, 11 oz. $2, 23 oz. $4, 50 oz. $8, by mail.



Also Specific for

SOUTHERN CLIMATIC FEVER

Same price and same quantity as above.

SAFETY HARD RUBBER MILK TUBES with hole in the end, and DILATING PLUGS

(Patent applied for.)

My Hard Rubber Tubes and Hard Rubber Dilating Plugs supplant all kinds of metal tubes. No blood poisoning or bruising. No dropping out of teat by its own weight. Two hard rubber tubes, 2 and 3 inches long, and two plugs $1.50 the four—and also one bistuary and two plugs $1.50 the three. By mail, the whole set $3.00. In writing for medicine, please say if the cow does or does not come in heat—as the medicines are as different as fire and water.

Dr. WM. HORNE, Janesville, Wis.

Returns From Robert's Dairy Last Year.

This dairy is kept on our farm, but is owned and managed by our son. In 1897 the average yield of milk per cow, as reported in these columns, was 6,440 pounds, taking into account all cows kept through the year. The yield for 1898 was 7,135 pounds per cow. Ten cows were kept through the year and milked through the season, and averaged the above amount of milk. The average time of milking was 314 days. Among the ten was a full-blood Holstein two-year-old, that came fresh last spring and gave 6,881 pounds of milk in 312 days. One cow gave 9,298 pounds and the next best one, 8,569 pounds. The poorest milker produced only 5,464 pounds. It was the intention to sell her for beef in the fall, as her yield of milk is too low, but before it was done the price of beef locally dropped, and she was milked through. Besides the above mentioned ten cows, there was a two-year-old that came in late, and up to February 1 gave 5,242 lbs. of milk. Some cows were turned off in summer or early fall, and others were bought fresh, so their record cannot go in with the above, as they were not milked through the year. The feed was permanent pasture through the summer season, and 2 to 3 pounds of wheat bran per day when the flush feed of June was gone. There was no soiling done. The winter feed was hay and grain, mostly wheat bran, with some corn meal. We do not advocate permanent pastures where land is valuable and suitable for tillage, nor can one depend on it for summer feed, where it takes five or six acres to feed a cow, and where the grass soon dries up Our pasture is moist, moderately rich land, not very suitable for tillage, and cost but $19 an acre. Under these circumstances the permanent pasture is profitable.

The average yield of milk per cow is given in the dairy sections of the East, where the writer is, as 3,000 to 3,500 pounds. Probably a good many readers of th *Practical Farmer* keep more or less cows. Do you get 6,000 to 7,000 pounds of milk per cow? If you do not, I would like to help you to. It is not a very difficult matter and helps the returns wonderfully. We have no silo or anything beyond the reach of any farmer. But do not construe this as against the silo. First, there are the scales to test the cows. Weigh the milk twice a month and you can come very close to what they are doing in a year and know which to sell. Then keep them warm and comfortable in the stable and give them water not colder than 50 deg. F. During the late cold weather our stable did not get below 52 deg. F. You can batten and line with paper or straw any old stable so it will be warm. Then feed the cows a fairly balanced ration, as was recently described in these columns.

Of course you will always be kind and gentle with the cows. Such management will soon enable one to dispose of poor cows, and increase his average per cow to 6,000 or 7,000 or more pounds. Then when you have some good cows selected out, get a full-blooded sire and raise some choice heifers, and go higher. There are large dairies that have got up to 10,000 pounds average, per cow, in this way, in a few years. This is the doctrine the writer has always preached, and the above figures are given to show our practice and encourage others. Robert has a full-blood Holstein sire, and is raising the calves. The question was once asked about the per cent of butter fat in the milk given by these heifers. It is high enough so no complaint has ever come from factory or city, and that is all we care for. Milk is sold in Cleveland, Ohio, now. Some farmers are anxious to have a cow that will bring considerable for beef, when they are through milking her. Robert bought two cows for $23 33 a head two years ago last fall. One was beefy, the other a typical milker. The beefy cow when fresh gave as high as 50 pounds a day at first, but ran down in yield very fast after two months. She was sold last summer for beef, bringing $38. The dairy cow in the two years gave $38 worth more milk than the other. and he has the cow, too. T. B. Terry.—*Practical Farmer.*

C. P. Goodrich at the Indiana Dairy Association.

In his address at the Indiana Dairy Convention, Mr. Goodrich stated that in educating an animal to become a good dairy cow must begin with the young calf. Muscle-forming food should be fed, such as bran, oil meal, skim milk, etc. Educate the calf on muscle-forming food as much as possible. Begin to feed the calf with skim milk and a spoonful or two of oil meal, then give a few whole oats to follow. Nice clover hay should be available. Feed skim milk six months or so. He wants an animal to come in milk at two years. Give the heifer a good box stall and plenty of straw to calve in. After calving, give her warm water—not cold. Take calf away gradually, say in two or three days. After calving, feed for awhile only a little grain, and then depend mostly on bran. After two weeks, you can begin to feed to full capacity. Feed a variety. It is desirable to have a balanced ration as nearly as can be. Quotations were given from the Wisconsin bulletin of 100 feeding rations, showing how some so-called successful feeders combined dairy cattle foods. Mr. Goodrich has found a production of two pounds of coarse food to one of concentrated as most satisfactory. Succulent foods are important. Of Woll's 100 feeders, 65 fed ensilage and two roots. If we cannot have green grass, we should feed either ensilage or roots. It has paid Mr. Goodrich to feed a little bran or corn meal in summer. His cows produce 50 pounds more of butter per animal the summer when fed grain than they did the summer before when no grain was fed. His grain cost five dollars, and thirteen dollars was derived from the butter, showing a good balance in favor of the grain. Do not feed every cow alike. Mr. Goodrich's standard feed is 32 pounds silage, 5 pounds clover hay 5 pounds corn stover, 8 pounds wheat bran and 2 pounds cotton seed meal. Lighten up on the feed of some cows, and increase on others. If she gives more milk by more feeding, increase.

April's Make of Oleo.

Forty Per Cent Greater Than That of April, Last Year.

April's make of oleomargarine in this internal revenue district, does not show as large an increase, as did several months preceding; but still, compared to April of last year, the output last month was 40% greater. Figures in the office of the internal revenue collector, in this city, place the output of the factories at 60 316 tubs of 50 pounds each. The make during April last year, was 42,559 tubs. For the ten months beginning with July 1st, 1898, the make aggregated 671,895 tubs, and for the corresponding ten months of the preceding year, it was 357,137 tubs. An increase of nearly 90% is, therefore, the remarkable record, the output of Chicago oleomargarine factories has made this year.

This record is in excess of any other year in the history of the business, the only year approaching it was in 1894 and 1895. For the ten months ending April 30th, 1895, the output was 589,961 tubs. From that time until the present year, the output decreased.

One less licence to retail oleomargarine was issued last month than in April, 1898, which, considering the larger output is rather remarkable. Seventeen licences were issued last month, and eighteen in April, 1898. For the ten months this year, the total engaged in retaling in this district is 1,702, against, 1,029 to whom licenses had been issued up to May 1st, 1898. In the number of retailers, as well as in the output, this year's record is ahead of any preceding year in the history of the business.—*Chicago Produce.*

Bone Meal for Stock.

The European Experiment stations are testing the value of bone meal with encouraging results. Recent trials of feeding young stock have been reported to the Societe Nationale d'Agriculture of France, appear to leave no doubt as to the value of bone meal. The bone dust employed as an addition to the feeding ration is known commercially as *poudre d'os vert*, that is, the powder is produced from raw bones simply dried in the open air and not treated in any way with chemicals. A calf 164 days old, weighing 478 pounds, received per day 1½ pounds of skim milk, 3½ pounds of oats, 3½ pounds of hay and 3 pounds of beets. On this ration, it increased fifty pounds in twenty-four days. Bone meal 4 ounces daily was then added to the ration and the calf increased 80 pounds in the twenty-four days, giving a gain of 30 pounds in twenty-four days by the addition of 6 pounds of bone meal. The bone meal promotes digestion of the food and increases the formation of bone, meat and muscle.—*Journal.*

Milk Preservatives In Michigan.

The agitation in Detroit over the use in milk of preservatives injurious to the human digestive apparatus, is being watched with satisfaction by the state food and dairy department as an agitation likely to be productive of wholesome results.

In the latest bulletin of the department an especial warning is conveyed to the public against the use of these preservatives Attention is called to a letter purporting to be signed by a mother which, the bulletin says, has been sent broadcast through Michigan. An extract from the letter is the following:

"A mutual friend desires me to write you, as you have a large dairy and creamery. You know better than I, perhaps, the necessity of having pure milk for babies and for household use. Now, as a mother and possible customer of yours, I want to say a word about this. Many times I have been made nearly frantic by having milk spoil just when I needed it the most for baby. My doctor told me of a preparation, made in New York which would keep the milk fresh and sweet till drank. It is harmless and cheap. I tried it and can vouch for it. I brought up my baby on milk in which a preservative was used, and a healthier and plumper baby for its age would be hard to find."

Directions as to how a designated brand of preservative may be secured are given in the letter. For $2, it says, enough to preserve 5,000 quarts of milk, and confer a blessing on mothers can be obtained.

The departmental comment on the letter is about the hottest stuff that has been printed in some moons in a purely official publication. This is what is printed in the bulletin just below the letter:

The foregoing is a deceit and a fraud of the vilest kind. Masquerading under the assumed name of a woman and clothing the counterfeit signature with the sacred mantle of American motherhood, this company seeks to promote the sale of its product in the very channels where its use will most imperil the health and lives of the children of our state. Can it be that the demands of commercial competition and love of gain warrant any human being to such despicable depths of deceit and falsehood?

The use of acid preservatives in milk is dangerous, and we question whether a chemist of repute can be found in the United States who would countenance its use in milk for the feeding of infants.

We warn the milk dealers of the state, many of whom in the past have used these preservatives, of the dangerous character of this practice.

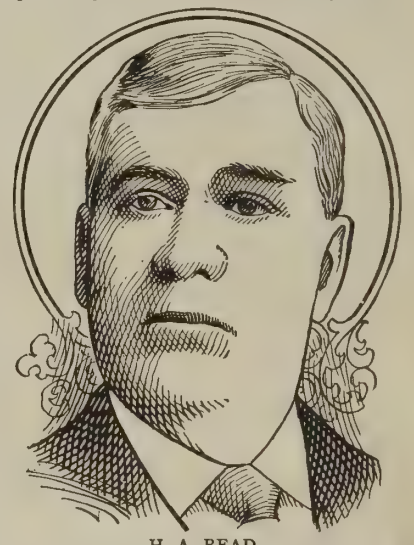
The department, through its dairy inspectors, will make a special effort this summer to detect the use of preservatives in milk sold for consumption, and we are determined that an arrest and prosecution will be made in each and every case found.—*Detroit Evening Journal.*

ILLUSTRATION.

We are showing herewith a machine which reduces the labor of hay-making to the very minimum. They are manufactured by the Keystone Manufacturing Co., of Sterling, Ill., who are well and favorably known to our readers. This Keystone Side Delivery Rake takes up the hay cleanly from the ground, and delivers it into a long, continuous, light windrow ready to be carried up by the loader.

It rakes cleanly, but does not take up dirt, stubble, manure, etc. It is said to be of easy draft, and is well and strongly made of the best material throughout.

The Keystone Hay Loader loads the hay direct from the windrow as it is left by the rake. It dispenses entirely with the services of an extra man, and one man and a team will handle more hay with its aid than three men can handle in the ordinary way. Another leading feature in the use of this machine is the quality of the hay. They work so rapidly that all hay can be taken in when it is at its best. They easily save their price in a season of "catchy" weather, when fast haying is a necessity. Write the Keystone people for circulars, etc., and look into their merits and advantages before the haying season opens.



It's easy to haul a big load up a big hill if you grease the wagon wheels with

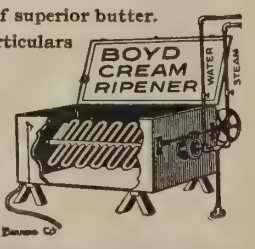
His Rupture Cured

C. & N. W. ENGINEER RESTORED BY THE WONDERFUL RICE METHOD.

Member of Waseca, Division No. 9 Tells How He Was Cured.

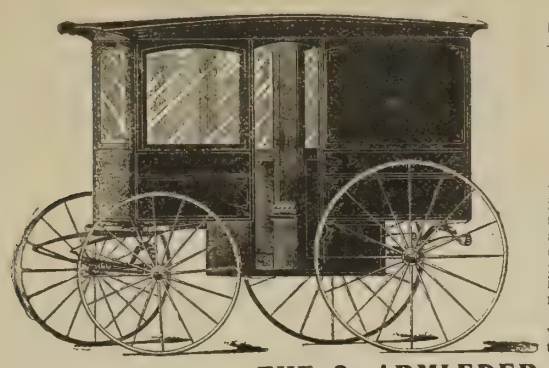
One of the old timers on the C. & N. W., having been in their employ over 29 years, relates some very interesting facts about how he cured himself of rupture by the well known Rice method. His name is H. A. Read, a member in good standing of Waseca, Division No. 9, B. L. E., so what he says for the benefit of other railroad men who are ruptured, can be relied upon as truthful and of value. Mr. Read says:—"I had as bad a rupture as you will run across in many months,



H. A. READ.

but the Dr. Rice Truss and Lymphol cured me. It was a hard rupture to hold, as I had to jump on and off my engine so often, the spring and other kind of trusses I wore would shift and let the rupture out. But the Rice truss fitted me exactly, and after the first night I wore it I knew it would cure me. I went to sleep feeling like a new man as the truss hold my rupture, no matter what I did or the way I moved about. I never lost one hour from work and as I am a railroad engineer it means considerable to be laid up with a rupture. I have saved a hundred dollars already in the time I have made up, and I shall always recommend the Rice cure with a grateful heart." Sincerely, H. A. Read, Waseca, Minn.

The Rice method is a perfect fitting truss, the only one known, and a marvelous healing lotion that securely knits and binds the broken muscles together making the cure complete and permanent. Every ruptured railroader should write to Dr. W S. Rice, 353 K Main St., Adams, N. Y., and he will send a complete and illustrated series of pamphlets showing conclusively that his method cannot fail to cure. It is home treatment at small costs, without pain, danger, operation or an hour's detention from work. Do not fail to write for either yourself or someone you know to be ruptured.



Well Pleased.

A Perfect Milk Wagon

On a Perfect . . .
Short Turning Gear

WE make the only drop center wagon that has a self-balancing, short turning gear. All parts are wrought iron forgings. It is so plain and simple that it can't get out of order and if any part should break, any country blacksmith can easily repair it. All other wagons of this kind have complicated gears, and mostly made of cast iron.

Write us for our Catalogue, which fully illustrates and describes this wagon and 10 other styles.

THE O. ARMLEDER CO., Cincinnati, Ohio.

THE ONLY LOW-DOWN

Short Turn, Straight Bottom, Short Coupled, Light Draft Wagon on the Market.

20 INCHES FROM GROUND to bottom of body. Will turn as short as any cut under reach wagon. Strong construction, nicely finished. ☞ Send for Catalogue, prices and terms. Wagons for carrying bottled milk a specialty.

THE NEW BOOK
Feeds and Feeding

By Prof. W. A. HENRY.
Wisconsin Experiment Station.

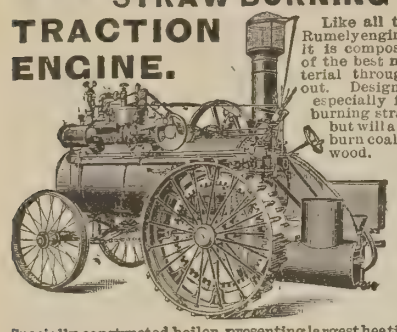
This book should be in the hands of every stock feeder in the country. Every reader of HOARD'S DAIRYMAN ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

or

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:



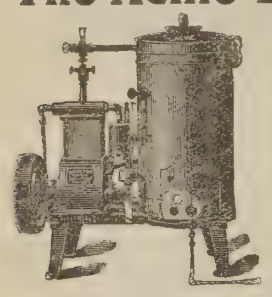
"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehensive from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be refered to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price $1.

THIS IS THE NEW

RUMELY STRAW BURNING TRACTION ENGINE.



Like all the Rumely engines it is composed of the best material throughout. Designed especially for burning straw but will also burn coal or wood.

Specially constructed boiler, presenting largest heating surface. It is a quick steamer. One of remarkably high power and efficiency, requiring the minimum amount of steam. Five-foot drive-wheels with 16-inch face. An efficient spark arrester prevents all danger from fire. The usual Rumely high finish. We make also other **traction engines, portable and stationary engines;** the famous **"New Rumely Thresher," Horse Powers** and **Saw Mills.** All are fully described in our Illustrated Catalogue—FREE.

M. RUMELY CO., La Porte, Indiana.

ON THE MARKET TEN YEARS.

Department H, PATERSON PARCHMENT PAPER CO., Passaic, N. J.

As a Milk Clarifier.

Numbers of the SHARPLES TUBULAR SEPARATORS are being used by extensive milk bottlers and milk dealers for clarifying their milk without extracting the cream.

Any cream separator will, to a greater or less extent, clarify the milk passing through it, but in most cases to a very limited extent, or in an ineffectual manner. While clarifying milk, the cream should not be separated and again mixed, or an inferior product will result. The whole separating space of the bowl should be constantly utilized or the machine will be ineffective. The bowl should be simple in construction and the course of the milk direct, to prevent, as far as possible, the frothing of the milk.

The milk should be brought under the greatest centrifugal action, else dirt alone will be extracted, and disease germs and clotted material left in the milk.

THE SHARPLES TUBULAR SEPARATOR

IS ESPECIALLY EFFECTIVE AS A MILK PURIFIER.

It can be changed from a cream separator to a milk clarifier in two minutes.

It separates filth and disease germs without separating the cream and milk.

The whole separating space in the bowl is fully utilized, and the milk is brought under a centrifugal force over three times as great as in any other separator.

The bowl is simple, easily cleaned, and a minimum of froth results. No type of bowl other than the TUBULAR will accomplish corresponding results.

If interested, write us and we will fully explain the reasons for this, so that they may be readily understood. Space here is too limited for the purpose.

And as MILK and CREAM SEPARATORS the TUBULARS STAND PRE-EMINENT.

Reading notices, 50 cents per line (nonpariel measure) each insertion.

If dirt gets in the milk, you cannot strain it out, nor wash it out, nor brush it out. It is there to stay, to make mischief in the milk, taints in the butter and only a poor quality of cheese. In every case your products will bring lower returns. Why then when you know what the result will be do you permit dirt anywhere in or about your dairy?

A new fraud has just made its appearance in Denver, Col. Parties in that town advertised a method for making artificial milk and according to accounts were very successful in finding victims. "The fool and his money are soon parted," and there seems to be an unusual number of the above genus in connection with the dairy, or there would not be so many butter nostrums, fake separators, poisonous preservatives, *et id genus omne*, continually on the market. As a general thing, the poorer the bait the more remunerative are the returns to the swindler. The dairyman gets experience for his money, which is a rather poor return.

If all the professors in the country should unite in declaring that food preservatives are harmless, we should still refuse to acknowledge the propriety of using such compounds. First, because we want to know what we are eating, and second, because no chemist can, by means of test tubes and solutions, decide what the human stomach will do when dosed with preservatives for any length of time. The doctors have been studying the human stomach for, lo, these many years, and yet are almost helpless when that same instrument begins to misbehave. The most they can do is to coax it a little until it comes back to its proper course, of its own accord. Yet they do not hesitate to declare the innocence of strong chemicals when taken into the stomach as food preservatives. They do "protest too much" and take too great an interest in the affirmative side of the question to be classed as thoroughly unprejudiced witnesses.

The Radiator is now on exhibition in the city of New York. This is the most modern example of advanced dairy machinery. It combines in one machine a separator, churn, pasteurizer and cooler. The butter produced by it is of course sweet cream, and as such has but a limited market. It is claimed that the butter can be ripened by allowing it to stand in butter milk, from which the butter will take up the flavor of ripened cream butter. It is stated that the machine is somewhat extensively used in Denmark and other dairy countries of Europe.

It is an expensive machine, and in the light of experience with somewhat similar machines in the past, it is evident that the American butter maker will wait for a thorough demonstration of its worth, before investing

JUTLAND CATTLE.

A Bull of the Black and White Race.

PLAIN TALKS ON BACTERIA AS APPLIED TO FARM PROBLEMS.

[By Prof. W. L. Russell.]

Second Series, XVIII.

BLACK ROT OF CABBAGE AND ALLIED PLANTS.

It is noteworthy with bacterial diseases of plants, as well as those of animals, that certain specific diseases are found in certain families of plants. Thus the fire blight is peculiarly a disease of pomaceous fruits (pear, apple, etc.). The disease here to be considered is one that affects those plants belonging to the mustard family. On the until a few years ago, but within the past two years, a fairly satisfactory life history of the malady and its cause has been worked out independently by Smith, of Washington, and the writer, working under Wisconsin conditions.

The disease makes its first appearance on the edges of the leaves, these parts assuming a parchment-like texture. The progress of the malady is to be noted mainly along the veins of leaves, these becoming blackened by the growth of the germ. After the trouble works its way back into the main stem of the plant, it cuts off the water supply, causing the tissues to wilt and finally die. Under the influence of the disease, the growth of the plant becomes dwarfed, sometimes the head failing to form. The disease is apt to be worse in the fall, in which case the heads may suffer from rot even after growth is practically complete. This frequently happens where cabbage are stored in cold storage during the winter. The disease can be quickly detected in these by an inspection of the stem. The least trace of blackened fibers in the stem should lead to the rejection of the head, for if the interior is affected ever so little, it is sure to rot in storage.

JUTLAND CATTLE.

A Cow of the Black and White Race

cabbage and its close relative, the cauliflower, the disease is of most importance from an economic point of view, but turnips, kale, kohl rabi, and bagas are also invaded by it. Among the wild plants, the common wild mustard is also affected.

Some years the disease is very wide spread, causing heavy losses among the truck growers throughout the United States; then again, the virulence of the disease subsides and the losses in the same regions may be trivial.

APPEARANCE OF THE DISEASE.

The disease is relatively a new one, not having been noted by growers until the early part of this decade. No attempt to study it from a scientific point of view was made

During the last few years, the disease has been especially severe in Wisconsin in the cabbage growing regions in the neighborhood of Kenosha and Racine. In 1896 in these two counties, experienced growers estimated the loss to be upwards of $50,000 or $60,000. Throughout many of the northern states, the disease has been reported, but it is to be said that it varies much in intensity from year to year.

CAUSE OF THE DISEASE.

Many notions have been advanced to explain the cause of this disease, but none of them until recently took cognizance of the infectious nature of the trouble. Since the isolation of a specific bacterial form from affected tissues, and the subsequent inoculation of the same into healthy plants with successful results, there is no longer any doubt but that the disease is due to the ravages of the bacteria. A study of the organism in relation to its host reveals many striking and interesting features, a knowledge of which is of great service in formulating proper methods of control.

HOW THE ORGANISM FINDS ITS WAY INTO THE HOST.

This germ has a most peculiar way by which it is able to establish itself in the plant. Every one has frequently noticed glistening water drops on the edges of cabbage and cauliflower leaves. Generally these are supposed to be dew, but as a matter of fact they are drops of water that are forced out of the tiny openings called water pores, that are situated on the edge of the leaves. When there is an abundant supply of moisture in the ground, and the air is quite saturated, the vapor of water that is always leaving the plant at these points is excreted in liquid form.

Now, suppose that there are disease germs of this sort in the neighborhood. Perchance they may have come from plants already affected, or from the ground. In any event, they are readily disseminated by the wind, and as they are blown about in the dust, they are caught in these tiny drops of water. In these they multiply, and so find it possible to work their way into the fine veinlets, and be distributed.

Then again insects may function as distributors of disease virus. Gnawing and biting insects, particularly, chew off portions of the leaves, thus exposing the more susceptible tissues to infection.

TREATMENT OF THIS DISEASE.

Treatment of a disease of this sort should be more preventive than remedial. After the disease germ has invaded the main stem of plant, no known agent can effect a cure. It is possible, however, to prevent the organism from gaining a foothold. This may be done by impeding infection by cultural treatment, or by checking its spread after infection has once occurred. The disease can only be produced if the specific germ is present.

In diseased tissue the organism exists in large quantities so that care should be taken to destroy plants already affected. Throwing such refuse on the manure heap, and carting it back to the fields is sure to give conditions favoring infection. Where a field becomes badly infected, rotation of crops should be practiced. Great care should be taken in planting healthy plants. If the soil in seed bed becomes infested, the young plants are pretty sure to develop the disease, and each affected plant becomes in the field, a new centre of infection.

Where the matter is taken in time, the disease can be practically checked by the removal of affected leaves, if this is done before the main stem is invaded. With a crop worth $75 to $150 per acre, it is well worth spending the time to keep the disease in check as can be done in this simple way.

Peanut Butter.

A new factory has just been put into operation in Kokomo, Ind., for the manufacture of butter from peanuts, says *St. Louis Globe Democrat*. For a year a more Lan Brothers, of that city, have been working on a process of making butter from the peanut to compete with the product of the farm cow, and have succeeded in producing the desired article. At the present price of the nuts the butter can be sold at 15 cents per pound. The process of manufacture is no secret. The nuts, after the hulls are removed, are carefully handpicked and faulty kernels removed. They are then roasted in a large rotary oven. Again they are gone over by hand for the removal of scorched grains. The nuts are then put through a mill and ground as fine as the finest flour, the natural oil in the grains giving it the appearance and consistency of putty as it leaves the mill, except that it is more of an orange color. By the addition of filtered water, to reduce it to a more pliable state, the butter is complete, no other ingredient, not even salt, being used. It never grows rancid, and keeps in any climate. It is put up in one, two, five, ten, twenty-five and one hundred pound tin cans and sealed. The new butter is already in great demand at sanitariums and health resorts.

REPORTS from Kansas state that many of the creameries in that state report greatly decreased milk supplies, some fifty per cent less than last year. The causes which lead to this result are low prices of butter and the high prices which beef cattle are bringing. This but illustrates the great hazard of building creameries in a community where the farmers are not, nor likely to be, dairymen in a sense of the word that will make the business profitable for them or the creamery.

A NOTABLE SALE OF JERSEYS.

The long time famous herd of Jerseys, owned by Mr. T. S. Cooper, of Coopersburg, Pa., was sold May 30th. This sale was in many respects one of the most important which has taken place for several years. Seventy-two animals were sold, bringing within a fraction of $200 a piece. At the head stood the bull, Pedro's Royal Marjoram 28560, which brought $1,100; sold to the estate of A. B. Darling, Ramsey, N. J. The bull, Peter Cooper's Pedro 53524, was sold to Maj. Henry Alvord, Chief of the Dairy Division, at Washington, for $800. General Marigold 45486, a three-year-old bull, sold to Biltmore Farm, Biltmore, N. C., for $800.

All lovers of fine dairy cattle, without reference to breed, will lament the dispersion of this magnificent herd, if it means that Mr. Cooper is to relinquish his interest and public work in the problems of dairy breeding. But few men in the nation have done more to demonstrate what was true and false in the theory and practice of breeding dairy cattle. Immense good, of course, will follow the wide spread dispersion of these cattle, all of whom represent the molding hand and brain of a past master in this great art.

OTHER OLEOMARGARINE FALSEHOODS.

A more causeless or inexcusable falsehood was never coined than that set afloat by the so-called *Country Gentleman*, to the effect that the officers of the National Dairy Union are using or have used "that organization to blow the trumpet of their private enterprises." On the contrary, the officers referred to are not only giving their time and means, but are taxing their "private enterprises" as well, to further the objects of the Union. These objects are to secure what is believed to be, right legislation for the protection of the dairy interests of the country.

What they desire and what they are working for above anything else, is the passage of national and state laws that shall effectually prevent the fraudulent sale of oleomargarine at wholesale or retail, or to the individual consumer in hotels, restaurants, boarding houses, and private families. These officers have given fair and convincing proof of their single minded devotion to these objects.

In the pursuit of these objects they have met plenty of men like the editor of the *Country Gentleman*, who have tried to prostitute this great central idea and purpose to politics or some other equally selfish purpose. The whole question in New York, today, is so prostituted and juggled with, for no other purpose than to make the crusade against oleomargarine serve the political ends of a certain party boss in that state.

His efforts to elect the next speaker of the House of Representatives, which Western dairymen have taken a hand in defeating, was a part of the general New York scheme.

In furtherance of such traitorous ends the *Country Gentleman* has lent itself to the disreputable purpose of spreading falsehood, and lies by inuendo, against the officers of the National Dairy Union, that it may aid its big boss to shield his oleomargarine friends from legislation which they fear.

Of near kin to its other falsehoods, and given repeated currency in the same degenerate sheet, is the triple lie by inuendo that HOARD'S DAIRYMAN was about the last paper in the country to advocate the passage of the filled cheese law,—that it is not opposed to the use of "preservalin" and such like compounds, and that it has not yet said the first word "against that other rank iniquity, renovated butter."

The thousands of readers of HOARD'S DAIRYMAN, in New York, know full well the utter falsity of such charges, and they cannot fail to soon know why the *Country Gentleman* has turned traitor to their highest material interests.

FOOD TO BE USED WITH SKIM MILK FOR DAIRY CALVES.

We notice that many of our exchanges are publishing extracts from Bulletin 35, of the Iowa Station, which gives the record of an experiment made with 12 calves for 74 days. The calves divided into four lots.

The experiment was made to determine what was the best food to mix with separator skim milk to promote the best growth. The conclusion was that the best and cheapest admixture was corn meal. But our exchanges generally leave out one very important fact brought out in the bulletin, by Prof. Curtis, and that was that the experiments were made to secure the best growth possible *for beef* results, not milk.

On that point Prof. Curtis expressly says:

"To develope and grow to maturity dairy-bred calves for the block, or calves of positive beef tendencies for dairy purposes is *worse than folly*.

It will also be unsatisfactory to grow both beef and dairy calves *by the same method*.

The beef bred calf should be fed to constantly maintain from birth to maturity a good, even covering of thick flesh.

To grow a dairy calf in the same manner however, would prove disastrous to dairy production, no matter what excellence may have been inherited."

Our readers will remember that in our reply to Mr. Crehore, on page 268, under the head of "Fattening Heifers," we spoke of the peculiarly deadening effect of corn meal on the mammary organs, and functions when fed in too large quantities. These organs and functions in the heifer calf should always be considered as in embyro. How they will be developed depends very much, as Prof. Curtis intimates, upon the way the heifer is fed. If she is fed largely on carbonaceous food, especially food like corn meal, the result will be to weaken and ensmall those organs.

The honey bees understand the subtle effect, or developing character of food. By a most wonderful skill that exceeds all human comprehension, they make either a neuter or a queen bee by the use of a certain kind of food.

By the same use of food we can either develop or decrease the mammary power and capacity of the heifer which is to be the future cow.

NEW HAMPSHIRE AROUSED.

The New Hampshire State Board of Agriculture has called a meeting of the superintendents of all the creameries in that state, to be held in Concord, June 20, to discuss the oleomargarine situation.

The circular issued says in part:

"Fraudulent sale and use of imitation butter in this country is increasing annually, and has a very serious effect upon the demand and price of genuine dairy products. We venture the assertion that more than $100.000 is annually lost to milk producers of New Hampshire, from the fraudulent sale and use of oleomargarine, butterine and other imitation dairy products, masquerading as butter. Farmers of this state should unite and demand the rigid enforcement of the law of the state regulating this matter, and call upon Congress to enact such legislation as will secure protection to the farmers of the country from the illegal use of imitation dairy products.

This is a right move on the part of the New Hampshire Board. It indicates clearly that the organization is loyal to its name, and is hostile, as it and all state boards should be, to all frauds and counterfeits in food. It is refreshing to know that corrupt party bosses, who receive money from the oleomargarine combine, cannot make the New Hampshire State Board disloyal to the dairy interests of the state and nation.

THE CHEESE OUTLOOK.

The prospects are fair for a strong cheese market all through the season.

The United States export is constantly falling off owing to the increased home consumption. In Canada the early spring make has been considerable lighter than last year. It is estimated the shortage will equal fully 4,000 boxes. The same causes that affect the butter and cheese production in the United States, viz: high prices of beef, are affecting the cheese production in Canada. We believe the present season will prove a fairly good one to all dairymen who stick to their calling.

Cedar Hill Farm Notes.

Making a Silo Tight—The Fly Question—Transmitting Power for a Silo Cutter.

ED. HOARD'S DAIRYMAN:—If Uncle John Patterson (every one in Missouri calls him Uncle) will take some flat, one-half inch battons, two inches wide with tarred paper strips to match, and tack them over those cracks, only nailing to one stave of silo, he will find silage will keep perfectly. These cracks are owing to the lumber being poorly sawed but most of them close up when silo is filled.

This silo question is a great one. I am in receipt of a price list from a manufacturer who offers to furnish material for a round silo 26x20, for $950.00 knocked down.

How many ordinary dairymen who read this journal, can afford a silo at this price? We have our material bought, 2x6's 36 feet long, laid down for $25 per thousand or $100 for the size we wish to build, or in other words, we could build eight silos with the money asked for one, which is something to consider.

If I were in Washington State I would build a silo of red cedar; if in Africa, rosewood or mahogany would do, but in this section, we can go to our lumber yards and, at a nominal cost, get our material of our merchant and he, in turn, will buy our butter or perhaps a family cow, which will even up matters. What I wish to illustrate is the fact that any material at hand will answer; saving freights and other charges not necessary to a good silo.

Some of those Texas flies have found me out and we must give them Texas treatment, or they may get homesick. Horn flies are the ones I mean. With a four inch paint brush and a can of Shoo-Fly my boys quickly go over our herd, giving them relief for two days at least, and at horse barn we have a can especially prepared for horses, which saves buying fly nets This horse protector is also Shoo-Fly. I have now used this preparation four summers, and all things considered, it is cheaper and better than anything we can fix up ourselves.

That rape is a great grower, at least, and to-day I pulled an armful for the chickens, and by the way they went for it, it is at least good for them. Will some one tell us about it as a cow feed?

Can any of the DAIRYMAN readers tell me if sufficient power can be got from an 8 horse engine, 70 feet from a Ross ensilage cutter, 16 inch knives and 30 ft. carrier, the power to be conveyed by a two inch shaft? Information on this subject will greatly oblige,

BUFF JERSEY.

Feeding Value of Ensilage.

ED. HOARD'S DAIRYMAN:—I have noticed lately that some of your correspondents are claiming that ensilage without much corn in it, is nearly as good feed as when all the ears are left in it. I can hardly believe this. Have been feeding ensilage for the last six years. Have always found ensilage rich in corn gives the best results. We had last summer one of the most severe drouths known in this section. The corn we plant for ensilage being a little thicker than field corn, had very few ears, while the field corn, small of stalk was fairly well eared. We filled one of our silos about one-third full with this field corn, with all the ears left on. When we came to it, in the course of our feeding, our cows immediately sprung up in their milk, while it took much less ensilage to satisfy them. Facts tell the story best. We have never had a cow made sick from eating ensilage, and if we had to do away with this valuable feed would quit dairying altogether.

Fourteenth Annual Meeting of the Holstein-Friesian Breeders' Association.

ED. HOARD'S DAIRYMAN:—The 14th annual meeting of the Holstein-Friesian Association of America, held in Buffalo, June 7th, was in every way an entire success. Forty-three members attended in person, and 230 by proxy. President Matteson, in his opening address congratulated his fellow breeders on the advancement of their favorite breed of cattle to first place in the estimation of the public.

The proceedings were entirely harmonious, the numerous amendments to the rules all being in the interest of greater efficiency and care in the maintenance of the herds in their purity. One amendment is of general interest, as it reduces the charge for registering imported animals. It has purposely been kept so high as to be practically prohibitive of importation.

The financial report of Treasurer Smith was as follows: Received from last year's board $14,810.52, from all other sources $23,417.37, disbursed $6,055.55, balance on

hand $17,361.82 or $2,551.30 over last year.

The entire membership of the association is 690 of which 84 have been added during the year, and 55 have come over from the Western Association which joined this association at the last annual meeting. A committee of the Canadian Association having been appointed with view to union also with this body, the meeting authorized the appointment of a committee to confer with them.

The attendance was very gratifying, ten states and Canada being represented. The meeting arranged for issuing challenges to the dairying public, soliciting competitive tests, which will probably be made public at the Pan-American Exposition in Buffalo, in 1901. This extended time is thought to be sufficient to disarm all opposition, and to make a valid excuse impossible.

Prof. H. H. Wing, of Cornell, who has made a large number of butter and butter fat tests of Holstein-Friesian cows, during the year, gave an analysis of them, showing pretty conclusively that it is not best to feed milch cows very high.

All officers were re-elected as follows: President, W. A. Matteson, Utica, N. Y.; First Vice-President, S. Burchard, Hamilton, N. Y.; Second Vice-President, W. B. Barney, Hampton, Iowa; Third Vice-President, W. S. Carpenter, Menominee, Mich.; Fourth Vice-President, W. J. Gillett, Rosendale, Wis.; Secretary, F. L. Houghton, Brattleboro, Vt.; Treasurer, Wing R. Smith, Syracuse, N. Y.

Adjournment to 1st Wednesday in June, 1900.

The Kansas State Dairy Association on Oleo.

ED. HOARD'S DAIRYMAN:—I respectfully submit the following resolution adopted at the regular session of the Executive Committe of the Kansas State Dairy Association, at its meeting held in Manhattan, Kansas, April 20, 1899:

Resolved. That the Executive Committee of the Kansas State Dairy Association, now in session, heartily endorse the movement of the National Dairy Union to secure a federal tax of ten cents per pound on all imitations of butter, colored yellow, and request the Kansas Representives and Senators in Congress to use all possible efforts to secure the passage of this bill. We believe this sentiment is endorsed by every dairyman in the State of Kansas.

H. F. JENSEN,
Sec. Kansas State Dairy Ass'n.

Give the Boy a Show.

The farmer should certainly have better judgment than the inexperienced boy of the budding mustache. Which should then order affairs on the farm? This is not so easily answered as might appear on the surface. Considering simply as a money making enterprise, an experienced brain at the helm is certainly the proper thing. What should we think of a pilot who turns over the helm to an inexperienced boy? Or to a lawyer who gives our case no personal attention and lets his inexperienced boy plan for our defence? We hire an expert to fix up our machinery, and he sends some one who is not posted in the matter. We kick. So when there is a difference of opinion between the farmer and his boy, the farmer naturally insists upon his own plans, for he has tested them, has longer experience and must suffer if things turn out wrong, for there are bills to be met and taking ill-advised risks is wrong and adopting plans which his judgment disapproves looks foolish to him.

For all that we hold that the boy should have his own way part of the time. Raising boys is one part of it. Producing beef and bread and butter is farm work, but the reason of producing beef and bread and butter is to produce brain and brawn from it. The boy is of more consequence than all the other stock. As a colt needs training, so does the boy. Tying a colt behind a wagon is a poor way to train him. Tying a boy behind the wheels in his father's head is a poor way to train the boy. Both boy and colt need to understand that there are proper things to observe and improper things to keep clear of, but neither can be educated without giving him the use of his own head. The boy's judgment needs exercising in order to develop it. Let him do some things as he thinks best, even if you feel positive you know a better way. The boy will learn in this way, and better than you can teach him by holding him in your well worn rut. And then again the boy may beat you and improve upon your own methods. Such things are not infrequent. Divide responsibility and honors with the boy. That is fair and it is the part of wisdom. E. C. BENNETT.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

GLOSSARY.

The terms used in this department of HOARD'S DAIRYMAN have the following significance:

RATION.—The total allowance of feed for twenty-four hours.

DIGESTIBLE NUTRIENTS.—That portion of the organic matter which can be digested by the animal and does not pass off through the bowels as excrement.

PROTEIN.—That part of the digestible nutrients which goes to the formation of lean meat, ligaments, hair, horns and the casein (or curd) of milk. It is generally believed, also, that protein may be, and many times is, converted into the fat found in milk. The basis of protein is nitrogen, hence the protein elements are frequently termed the *nitrogenous* parts of the food. They are also called *albuminoids*.

CARBOHYDRATES.—That part of the digestible nutrients which is the primary source of sustaining animal heat and furnishing the power for keeping the animal mechanism in operation. They are composed of the woody fibre of the plant and grain, and the starch, sugar, gums, etc., and in the published tables of chemical analyses are usually subdivided into the terms *crude fibre*, which is the least digestible portion of feeding stuffs and *nitrogen free-extract*, so-called because it does not contain any nitrogen.

ETHER EXTRACT.—That portion of the digestible nutrients which may be dissolved out of the food stuffs by ether. It is frequently called *crude fat*. Whether fat is actually digested and thus passed on into the circulatory system in a changed form or whether it is simply separated from the other elements and always maintains its identity is an unsettled problem. It can be used by the animal for maintaining the body temperature, and for this purpose is from 2.2 to 2.5 times more efficacious than the carbohydrates. It is maintained, by some, that the fat in the milk comes, largely, from the crude fat in the food, but ithas been demonstrated that it is not absolutely necessary, for this purpose.

CREAM DOES NOT CHURN EXHAUSTIVELY.

I have just begun to use a separator and am having trouble with churning. Do not get more than one half as much butter as it ought to make. Buttermilk looks as rich as when put into the churn. Cows are thoroughbred Guernseys. B. W. H.

Genoa, N. Y.

We think the trouble in this case comes from insufficient ripening of the cream. It should not be forgotten when commencing to use a separator, that the cream is both fresh and sweet, whereas in other methods of creaming it has stood for twelve to thirty-six hours on the milk and although perhaps not perceptibly acid to the taste, is well advanced towards a proper condition for churning.

Moreover, cream rising and resting on the milk for some hours ripens faster than when separated, because of the greater number of bacteria and their more rapid multiplication.

Therefore, all other conditions being equal, the separator cream should be kept somewhat longer than the cream and milk, or, put in another way, the time from milking to churning should be longer than when the cream is obtained by setting the milk. Of course, the ripening process can be expedited by letting the cream be kept a little warmer, or by using a starter.

SUPPLEMENTARY FEED FOR CALVES.

Please give me grain ration for Guernsey calves two months old, to be fed with separator skimmed milk and clover hay.

Cayuga, Co., N. Y. R. W. HURLBUTT.

There is nothing better than ground flax seed for this purpose—not the ordinary oil meal of commerce, but the full flax seed meal. Skim milk is a highly nitrogenous feed, and so is oil meal. One of the foremost Guernsey breeders in Wisconsin, uses Blatchford's calf meal, and, notwithstanding its apparently high price, is confident that it pays him to buy it. Bran, corn meal and oats are also used, and it is somewhat surprising how soon the young things will learn to eat whole dry oats and thrive thereon.

SWEET CLOVER.

Will sweet clover make hay of any value as cattle feed if cut when small? Would it be profitable if cut up and mixed with corn ensilage? I understand that in Germany they use it for hay, with satisfactory results.

Serena, Ill. J. M.

Sweet clover (*melilotus alba*) undoubtedly has very considerable feeding value, but for all that is decidedly inferior to the common and mammoth red and alsike clovers and alfalfa. Where these varieties will grow, it would be poor farming to raise the sweet clover as a regular crop. Its habit is to grow rank, producing large stalks and comparatively little foliage. In several states—Wisconsin among the number—it is classed as a noxious weed, and the farmer who suffers it to ripen seed on his premises, or the highways adjacent thereto, is liable to a penalty.

It is very efficacious as a soil renovator, having the power inherent in other legumes to gather nitrogen from the atmosphere, and to send its large tap roots into the most obdurate soil. Here they decay, as the plant is a biennial, and leave openings which materially assist in aerating the soil and in drainage.

Having enough of this crop growing wild to make it an object, we do not hesitate to advise cutting and curing it for hay. It is claimed that cattle do not relish it at first, but soon become quite fond of it.

CROSSING JERSEYS AND GUERNSEYS.

What would you think of crossing thoroughbred Jerseys and Guernseys? Would the cross be any improvement over either breed? W.

Jefferson, N Y.

Answering the last question first, we have to say that the mere fact of cross-breeding would not tend to any improvement, but we would rather accept such a cross, if necessary, than breed to an objectional sire, if the only object was to raise dairy heifers. Jerseys and Guernseys have so many points of similarity that interbreeding would not be likely to set up strong countercurrents, but the progeny would not be eligible to registry and if an exceptionally good cow should result, one could not dispose of her calves except at grade prices. Therefore, instead of recommending such breeding, we suggest getting a sire of the breed now in possession of the highest quality both individually and by inheritance.

CHEAPER ROUGHAGE WANTED—THE COMPLEMENT TO SILAGE.

We want to get cheaper forage than the home market supplies. Will some of your subscribers, in the alfalfa sections, tell us, through the DAIRYMAN, or direct, what good alfalfa hay can be bought for. Cow pea hay is $10 now, and often goes higher. I notice in Ed. H. Webster's article that $3 is the usual price for alfalfa. According to the analyses, alfalfa ought to be better than pea hay? Is this so? We expect to use it as complement to silage. You once said clover hay was the best feed to go with corn silage. Why better than alfalfa or cow pea hay?

Tennessee. WILLIAMS BROS.

Answering this inquiry in the reverse order of its statement, we may say that in the statement in regard to "best feed to go with corn silage," the word clover was used in a general and representative sense, rather than in a specific and limited way. Hay from common red clover, alfalfa, cow peas or other leguminous plants, is of approximately the same composition, and is all classed as nitrogenous, or rich in protein, alfalfa leading in this respect, but so closely followed by cow peas that different samples might easily reverse this order.

But a more important consideration for our Tennessee friends is that they should not suffer themselves to be dependent upon either home or other markets for forage. They can grow, not only common clover, but alfalfa and cow peas, abundantly and cheaply, and for the latter this is the most opportune time for seeding. If there is no other ground available, sow them among the corn as advised in the article we reprint, in this issue, from the *Southern Cultivator*.

COLOR OF CREAM.—SPEED OF BABCOCK TEST.

I run a hand separator and sell cream. After cream is run through it is immediately cooled to about 45° and kept so for twelve hours, and I am told that separator cream handled thus is not as yellow and not as acceptible to the trade as cream produced by a Cooley creamery from the same herd of cows and the percentage of fat being the same in both cases. Is this a fact, and is it so accepted by dairymen generally?

How does the average dairyman know whether the acid procured at a drug store is of the proper strength or density for use in the Babcock tester? How many revolutions is necessary per minute for an accurate test.

Deans Corners, N. Y. W. N. I.

The color of cream is not affected by the manner of separating. It will be just as yellow from a separator as from a Cooley can, provided the same kind of milk is used in both cases. The only difference between the two creams is that separator cream does not run as thick as Cooley cream of the same richness of fat.

The best way is to have the seller guarantee the strength of the acid.

It depends on the size of your machine. If the wheel is eighteen inches in diameter it will require a speed of 800 revolutions a minute. Twelve inches 980; 24 inches 700. Other sizes proportional.

OAT HAY.

Would you please tell me whether it is advisable to feed oat hay to dairy cattle, and give me your opinion about feeding middlings, shorts and bran. H. E. N.

Siskiyou Co., Cal.

Oat hay ranks about midway between the best timothy and the best clover, and, therefore makes a very satisfactory feed for milch cows. Of course it needs to be cut quite early, before the stalks become too woody. The same remark might be also applied to timothy and clover.

We do not quite understand what is meant by the last half of the question. There is a very deep rooted sentiment among many farmers that middlings make a better feed than bran. We are persuaded that there is no sound basis for this opinion when the two are considered by *weight* and not by measure. Bran is very light and bulky and unless one is constantly on guard over himself when feeding bran, the allowance is very apt to be scant. We all realize the difference between corn and oats when feeding and would not think of using the same bulk when feeding corn as when feeding oats. In fact, feeding by measure without occasional reference to the scales, is anything but exact, not to say scientific. At the same price we should prefer bran to middlings, and as a rule would discard shorts altogether, as they are apt to contain pretty much all the dirt that accumulates in the mill.

MILKING WITH DIRTY HANDS—SOAP FOR CLEANING DAIRY UTENSILS—DIVIDING PROFITS.

Do you consider it a decent practice for the milker to milk his cows mornings without washing his hands?

Is soap a proper article for cleansing cans in which cream is shipped?

When owner furnishes land, horse, dairy room and utensils and business is conducted on shares what part of expense, profits and stock goes to working man?

Tenn. E. M. K.

It requires no consideration to condemn such a practice at once. The success of dairying depends on cleanliness as much as on selection and feeding, consequently cleanliness of clothes and person is as much a necessity as cleanliness in the dairy surroundings.

Soap is not as good as soda for cleaning dairy utensils. Some soap is made of very poor and impure material, fat which has come rancid and decomposed. Such soap, if hard water is used, is liable to leave more impurities than it removes as it forms an insoluble compound which sticks to the sides of the cans.

There is no rule for adjusting the profits. It all depends on the agreement between the two men. It may be considerable above or below one half, according to conditions.

"How We Breed, Feed and Handle Our Cows—Results".

ED. HOARD'S DAIRYMAN:—In March of 1892, my father sold his first milk to a creamery. His herd was composed of such cows as he could buy through the country, and I think were below the average milkers of that day. The best cow of the lot was an old red cow—old, but bearing the marks of a most excellent producer—and a three-fourths Holstein cow, also an excellent milker. Afterwards two Holstein heifers, one a three-fourths, and the other a five-eighths, came into the herd and were fresh a year later. A few months at patronizing the creamery—milk then sold at one dollar to one dollar and fifteen cents per hundred pounds in winter—favorably impressed him with the idea of selling milk. So he sought to improve his herd by the purchase of a pure bred Holstein bull. The animal was not high priced, and his pedigree was not one that would place him in the list of rarely bred milk or butter bulls. From him all the heifer calves were kept.

At about this time creameries begun buying milk by the test, and, while father's test was an average one, public opinion had it that Holstein milk was extremely thin, and that the steer calves would not sell, so his attempt at breeding Holsteins was ridiculed to such an extent that this bull was replaced by a Short-horn of so-called "milking strain". Those were days when every breeder had "milking" Short-horns. After a season this animal became crippled and was killed; and was succeeded by a Polled Durham, whose sire and dam came from the celebrated Elgin district of Illinois, he also of "milking strain." At the end of a year his calves gave so little promise that he too was disposed of.

At this point, the firm became G. W. Horman & Son, and being convinced that we could produce butter fat at a greater profit than beef, we gave it first place on the farm. We set about to rear a dairy herd, and bought Violante's Gold-dust, a pure bred Holstein bull, and with him a pure bred cow and heifer.

The heifers from the first Holstein cross are the cows, aside from four pure bred ones purchased, which constitute the present herd. The herd is composed of two seven-eighths cows, one five-eighths, one three-quarters and the remaining half breeds. With one exception, the five-eighths cow, all are good types of the dairy animal. The average weight of these cows is probably 1,200 pounds, and of the entire lot only one is inclined to put on fat, and that not during the milking season. But she carries too much flesh to be an economical producer. They are good feeders, always hungry and the enormous consumption of each is recognized by the capacious stomach distended almost to deformity when filled. All are extremely quiet, and in several cases bordering on stupidity, yet sensible to all changes in surroundings or unusual occurrences about the barn or lot. In other words, they act and look like cows built for business, whose only occupation is the production of butter fat every minute of the twenty-four hours of almost every day in the year, and anything which tends to detract attention from the work, is sure to decrease the yield.

As producers these cows are not wonders, yet each is profitable, and, I believe, above the average cows. They are persistent milkers, and in several instances refused to be dried. Last year the herd—not a selected lot, mind you, but all the heifers from this first Holstein cross—produced an average of 309 pounds of fat, or 360 pounds of butter, and this year the yield will be increased. The average test of the individual cow is 3.9; the highest 4 9, the lowest 3.4. The average test of milk produced is 3.75 per cent fat. The largest producer of this breeding is a seven-eighths cow from the original three-quarter cow; last year giving 12,000 pounds of 3.4 milk or 408 pounds of fat equivalent to 476 pounds of butter. The next highest yield is from a three-quarter cow which with 4.5 milk produces as much fat as the other, for the first six months of the milking period, but is not such a persistent milker. These are records made on the usual feeds and care given the entire herd. In the hands of a competent feeder, and by forcing, they doubtless could be made to exceed these figures.

As stated, the first Holstein bull was succeeded by a Short-horn and from the latter's calves, three of the most promising heifers were selected for future usefullness in the dairy. The heifers came fresh and the result was gratifying from a beef man's standpoint. Indeed, they were beefy and on our feed took on fat like hogs, and gave very little milk. In no case was the milk season longer than five months, and after the first month in milk failed to pay for the grain consumed. But, we had hopes and gave them a second trial. Soon after the second calving they went to the butcher. God might have made a cow which could convert the same food into both milk and beef, but he never did.

In the case of one of these heifers I can make a comparison indicating the value of breeding for what you want. The original old red cow dropped two heifer calves in succession; one a half breed Holstein, the other from the Short-horn bull. The Holstein heifer with third calf produced an average 53 pounds of 3.8 milk per day for seven days, and for the same time the red heifer with second calf gave 27 pounds of 4. milk per day for the same time. The cows were half sisters, one producing 2.3 pounds of butter per day, the other 1.2; the first milking eleven months of the year, the second dry at five months. This instance only serves to demonstrate the value of a sire bred for milk and butter when the farmer is rearing a dairy herd.

In the fall of 1895 we bought Violante's Gold-Dust, a pure bred Holstein bull, from a cow said to have produced 22 pounds of butter in seven days, and we have chosen eight heifer calves from two lots of his calves and we know they will be as good milkers as their mothers, and we are reasonably sure they will be better. Four of these are yearlings and are showing up remarkably well. These were reared on skim milk with bran feed, from early fall to late spring, and were given roughness in abundance to develop stomach capacity. They were not allowed to fatten. It is with great anxiety we await their coming fresh a year from this time.

This herd of eight heifers, all better than three-quarters, and two are pure bred, will be headed by a wonderful calf we bought last spring. Our little kuowledge of improved blood created a desire for still more, so we purchased at three weeks old, May Overton's Metchtilde Sir Henry, the best bull calf we could buy, and with few equals in milk and butter breeding in America.

I would impress upon dairy farmers the absolute necessity of the selection of well bred males. The stronger the milk and butter breeding the greater certainty there is of securing profitable additions to the dairy herd. Eliminate all possibility of a poor heifer calf; it can be done. Again, do not buy an inferior bull. An animal costing $100.00 and if properly bred along milk and butter lines, is cheaper than one as a gift if of no especial breeding. A milk and butter bull capable of producing heifers worth $10.00 a head more as cows, will in one season, on a herd of fifteen cows, pay for himself and put hundreds of dollars in your pocket, if you continue in the dairy business. Heifers producing five or six, or even four pounds of average milk per day, more than their dams, should be regarded as a flattering improvement on a herd of common cows, for the first milk cross. I am not an advocate of the theory of persistent breeding up from common cows and common bulls; life is too short to undertake it. Any farmer can better afford to buy a good bull of some favorite milk breed, and get into the dairy business properly in from two to four years.

The rough feed consumed by our cows is such as can be grown on any upland farm in central Kansas, and the list includes all the principal drouth resisting plants. It is necessary that the dairy farmer grow such crops as are reasonably sure to produce a fair yield and so diversify his list that a complete failure is almost an impossibility. That this can be done has been demonstrated on our farm during a period covering the last six years which includes several drouths threatening destruction to every growing thing. A failure to grow an abundance of rough feed has not occurred on our farm. Aside from growing a variety of crops to assure a bountiful food supply, we grow a variety for variety's sake, and this too is necessary for the best results.

Sorghum and kafir sown thickly and cut before the seed matures make valuable, and to the Kansas farmer, almost indispensible fodder. Prairie hay early cut, oats in the sheaf, millet and alfalfa hay conclude the list which, for the western Kansas dairyman will afford a liberal milk flow if fed in the proper combinations with grains or concentrates rich in protein. This winter we are using our first alfalfa hay fed to milk cows, and while we are not securing the best results on account of our failure to cure it properly, each day of its use emphasizes its value. As a pasture, alfalfa affords an extremely early spring feed, and in the fall a more abundant pasture than rye. Again, fed either green or as hay, it is unequaled as a supplement to a short and dry prairie pasture, wonderfully sustaining and even increasing the milk flow during the critical times of drouth, which occur with considerable regularity in Kansas. Indeed, it is the dairy farmer's friend. It is an almost perfect milk food, combining as does no other plant we grow, the food nutrients in the proper proportion for succesful milk production. On our farm, it will soon become the principal hay for cows.

The feeds above enumerated are fed alternately and in such quantities as the cows will clean up nicely; in fine weather in an open lot, and on stormy days, and always at night, in the barn. In feeding we always consider the palatability of the food. Be it hay, fodder or grain, we try to feed it bright and clean, and served in mangers cleanly swept. We endeavor to make the feed extremely tempting, insisting always upon the greatest possible consumption by the cow. She must eat heartily and abundantly, and if the proper digestion and assimilation follows, the milk yield will be satisfactory. Milk and butter come from the food consumed, and if that be not large, the profits must be correspondingly small.

In the preparation of a grain ration we have experimented considerably during the past three years, and have concluded (1) that the grain ration depends entirely upon the roughness, and (2) that a ration which is successful one year is not necessarily so the next, for the reason that cows seldom go into the winter's feed in the same condition two consecutive years; and last, that a ration which will cause one cow to do her best at the pail will not produce such flattering results in the case of a second or third cow. The one great lesson learned is that the dairyman must deal with the individual stomach, the individual appetite, and not the herd.

When alfalfa hay is the basis of our feed, we use corn chop diluted with bran, or when sorghum or millet or kaffir corn constitutes the roughness, we partially balance the ration by the use of about all the best wheat bran the cow will consume, and, if she will eat it, a pound or more of linseed meal. We have had difficulty in getting cows to eat the meal, and have had, one time, to abandon its use, but this latter combination of feeds has produced our heaviest yields, and sustained the milk flow during the whole fall and winter season remarkably well. The foregoing combination of rough feed with four pounds of corn and cob meal finely ground, and six pounds of bran per feed is this year giving us more satisfactory results than bran alone has done.

During 1897 we used bran exclusively. The average quantity consumed per cow was 1.08 tons at a cost of $8.15. The cost of this bran could have been decreased nearly $2.00 had the winter's supply been bought in the fall instead of being bought as consumed. To us this cost appears extremely small, and we regard the cow that will not return a good profit on that amount of feed during the winter, as unfitted for dairy use. It seems strange, indeed, that so many farmers are content with a small milk yield when it could be doubled or increased by the use of cheap bran. Winter milk averages in price probably eighty cents per hundred pounds, while bran costs forty-five cents, at present, and one hundred of bran fed with good roughness, in a warm straw stable, will produce one hundred pounds more milk than no bran with poor shelter and poor roughness.

The idea of a balanced ration is hooted by many thoughtless farmers, but it is our observation that the nearer we approach a scientifically balanced ration, the more milk we get. The average dairy farmer cannot, or will not, go to the expense or painstaking of science, although I feel reasonably sure he would be repaid by so doing, if his cows were fair producers. Yet every farmer, with only a little care, can closely approach scientific feeding, so closely that a very little loss will accrue from the violation of the feeding standards.

No farmer who makes pretentions at dairying could have violated in a greater degree the teachings of our most successful feeders than ourselves, in that our rations include no succulence in the way of ensilage. We do not question the value of either; in fact, we are so much in favor of ensilage that the silo on our farm is not a great way in the future. Yet, we are well pleased at our results without it, and our work seems to establish the fact that the much written about beets and ensilage are not absolutely necessary to the production of milk and butter in good quantities and that at a profit. What we have done in the way of feeding, the poorest farmer in Kansas can do. Our system of feeding requires no bank account to support it. The cows do that.

To the Kansas dairyman the most critical period of the milk season is that of summer and fall, when from drouth or hot winds the pastures are short, or if not short, the grass is too dry to sustain the milk flow. Unless some good feed is given at that time, what

"The Mill Cannot Grind with Water That's Past."

This is what a fagged out, tearful little woman said in telling her cares and weaknesses. Her friend encouraged by telling of a relative who had just such troubles and was cured by Hood's Sarsaparilla.

The little woman now has tears of joy, for she took Hood's, which put her blood in prime order, and she lives on the strength of the present instead of worrying about that of the past.

Neuralgia—"I had dreadful neuralgia, miserable for months. Neighbors told me to use Hood's Sarsaparilla; it cured me perfectly." MRS. FRED TURNER, Barre, Vt.

Erysipelas—"My little girl is now fat and healthy on account of Hood's Sarsaparilla curing her of erysipelas and eczema." MRS. H. O. WHEATLEY, Port Chester, N. Y.

Hood's Sarsaparilla
Never Disappoints

Hood's Pills cure liver ills; the non-irritating and only cathartic to take with Hood's Sarsaparilla.

Not a Preservative

but a preventive. If you would have your milk keep sweet longer and be free from all objectionable odors, use a CHAMPION Milk Cooler-Aerator. It does its work perfectly and it's use does'nt violate any law—it doesn't need to be used on the sly. Our book "Milk" is free.

CHAMPION MILK COOLER CO.,
67 Main Street, - Cortland, N. Y.

might have been a successful milk season will become a disastrous failure. Fresh cows will so shrink that no quantity of winter feed will restore the flow. Cows fresh in the spring will often dry completely, or, at best, so shrink as to give an unprofitable quantity on the winter rations, and even the dry cow, the cow to calve in the early fall, will suffer from the scarcity of nutritious and milk stimulating food. Cows neglected at this time of the year, are loth to forget and will surely take vengeance on the careless owner by retaliating at the milk pail. At this time we give kafir corn or sorghum, green, night and morning; or Indian corn feed, with a good nubbin on each stalk, fed at this time, will never yield a greater profit. Alfalfa, fresh cut, or as hay, is an ideal feed.

After feeding green sorghum, we have not only sustained the milk flow, but have made such gains that its use was continued even after rains had put the pasture in reasonably good condition. In fact, the feeding of these green foods has been so highly successful in milk yield and so economical in production, that I believe the practice of the soiling system in the early fall will permit our small farmers to double their dairy herds and produce milk at a greater profit than under present practices. Dairying after the soiling system is not an impossibility in Kansas, and when she has become truly a dairy state, I predict that it will be practiced largely.

Next season all of our cows will calve in the early fall; in fact, none are fresh later than January of this season. The advantages of a fall cow are well known. She milks longer and gives a larger yield for a longer time, hence more pounds for the year. She is, or should be dry during the months of flies and greatest heat; the bulk of her milk commands the best prices of the year, and the low priced milk is produced at a time when feed is cheapest and labor and care is least, and last, the fall calves will make the best growth. So we dairy with fall fresh cows.

The success of the cow's milking season depends largely upon her treatment before being fresh. It pays to feed a few pounds of corn meal before calving, beginning six weeks before, and getting her into good flesh and strong. If the grass is not good, or sufficient to move the milk producing glands to activity, we begin feeding bran a few weeks later than the meal. We aim to have a cow so fed that she will be in condition to do her very best at production immediately after recovery from calving. A poorly fed cow will come fresh in a run down condition, having made no preparations for milking, and the farmer will spend a month or six weeks of valuable time after the cow comes fresh, feeding the cow to her capacity, and in nine of every ten cases he will fail to get so good a yield as if the feed had begun six weeks sooner. By careful, judicious feeding there is no danger in this process of treatment, and it will pay enormously. Professor Cottrell, of Manhattan, says, a cow allowed to give a low yield for two months after calving, cannot by any system of feeding known to him be brought to a high standard the remaining part of the year. If you are seeking the greatest returns from your cow, begin feeding before calving.

Our milking is done in the barn every night and morning of the year, and at as nearly regular hours as farmers' circumstances will permit. We weigh and test each cow's milk with such frequency that we are able to know just what she is doing. Years ago we began weighing milk through idle curiosity, but this demanded regular weighings, and the spring balance demanded the Babcock test—the one without the other is a delusion and a snare—and the two brought about tabulated records. Dairying without these simple means of ascertaining the real value of the cow is not conducive to the best results.

I know that a pair of spring balances hung in a convenient place in the barn will actually make a cow give more milk. They induce clean milking, and, if a good yield is shown one day, and a low one the next, he is a shiftless milker, indeed, who will not give the same feed or place the cow in the same condition as nearly as possible as that of the day of the high yield. The scales in the barn are a good thing for us, and will do much good for any one else. No farm work is so instructive or yields so great a return for a bit of intelligence as does dairying.

On cold mornings, our cows get a good feed of hay or fodder in the barn, and remain there until the sun shines bright and warm, or until watering time, when they are turned out and go to a spring three hundred yards distant to drink. On days of extreme cold, they are restabled immediately upon their return from water, and while ordinarily dairy cows are decreasing in their product, we have under these conditions kept up the flow and several times made gains. Our barn is a frame structure but warm, and the temperature seldom reaches the freezing point. It is fitted with swinging stanchions, which keep the cows reasonably clean, and make them comfortable.

The calves are kept under the same roof, in pens convenient for feeding and given skim milk warm from the separator after each milking. We think this method of handling the skim milk the ideal one. Its value at this time is fully 3 times greater than when it returns from the factory, and, to the man who seeks the most profit from dairying, the proper disposal of this product means many dollars to the income of each cow. Hogs and calves sufficient to consume every drop should always be kept. Hogs are the complement of the dairy, as well as of the feed lot. In 1897 the minimum quantity of whole milk we fed per calf was 450 pounds, an average of 12.5 pounds for 36 days, or to our lot of 12 calves 5,850 pounds of whole milk, equivalent to 218.79 pounds of fat, which, at prices paid by our creamery was worth $35.91 or $2 22 worth of fat consumed by each calf. These figures make calf raising for the first 36 days expensive; but by the use of warm separator milk and careful feeding of corn meal or oats with it, we get a calf started well in this world with whole milk not longer than ten days. As dairy farmers we are forced to look to every saving, and in this connection the farm separator is our greatest friend. It saves hauling, saves time, saves butter fat fed to the calves, makes more and better feed, and to summarize, pays a tremendous interest on the investment. Our separator is operated by a calf on a tread-power.

So, in a general way, I have outlined our manner of breeding, feeding and handling our cows, and have hinted at the results. In a measure, only, are we pleased with our work. We can do better, and will do it this year. The report which I am about to read is for the year 1897. It was made under circumstances somewhat adverse, and does not show the herd at its greatest capacity. Several immature cows were milking, while others calved in the spring, and the milk flow of these was checked by hot weather and flies, at a time in their period of lactation, when the yield should have been heavy. Also, the report does not take into account the milk used in the house. The report of product is:

Average pounds of milk produced per cow	8,263 1
Butter fat per cow	309.23
Butter (fat plus one-sixth) per cow	360.75
Value of fat at 16.375 cents per pound	$49.70

While the foregoing shows the actual product, the following reports the actual sales, calculated from the monthly creamery statements. The sales are:

Average pounds milk sold per cow	7,813
Butter fat sold per cow	292.4
Butter (fat plus one-sixth) per cow	335.9
Valve at 16.375 cents per pound	$47.48

The financial report may be interesting al so. The steer calves and undesirable heifers were sold at one year old and brought an average price of $25 per head. The choice heifers were not marketed, and we value them to-day as yearlings, at the price of a good milk cow. But, since we cannot estimate their real value, we place them at $25, stock prices also. Skim milk was returned from the creamery to the amount of 300 barrels during the year, at an average price of 12.5 cents per barrel of 48 gallons. And we place the feeding value at 25 cents per barrel above the cost. Then from 12.2 cows we received:

From the sale of butter fat	$590.39
Value of calves at $25 each	325.00
Value of skim milk	75.00
Total increase	990.00
Income per cow	81.17

New Jersey State Dairy Commissioner Geo. W. Maguire, in his recent annual report says that the work of his department for the year showed that a good deal of milk, especially during the summer months, had been preserved with acid, a large part thereof being a "remarkably strong antiseptic derived from wood alcohol." His investigations as to the extent of the use of that chemical, disclosed the fact that it was becoming almost universal. No professional certification of the unwholesomeness of such a compound is needed, but State Chemist Wallace and Professor Descher, who made the analyses, denounce the use of any preservative whatever, and agree that in the case of children, particularly, much illness is caused by the use of milk so treated. New Jersey is in this particular no worse off than New York and other milk producing states. There is sufficient testimony that like practices are common in them all, and that a remedy must be found and is very generally being sought in legislation absolutely interdicting any such process, and providing penalties of sufficient severity for its violation.

Food Preservatives from a Medical Standpoint.

The *Medical Record*, of late date, in discussing the question of "embalmed beef" as an army ration, has this to say about boracic and salicylic acids and adulteration of foods:

"As there is no proof to show that boracic and salicylic acids are absolute preservatives, it is fair to presume that the 'embalmed beef' was not only more or less decomposed, but was artificially 'doctored' beside. Thus the two conditions were combined to make the men sick. Aside from the reprehensible practice of adding chemicals to any kind of food, there is a positive danger in so doing, of slowly poisoning the unsuspecting victim. Theoretically, we may assume that either of the acids mentioned may not be used in sufficient quantities in any case to produce immediate deleterious effects, but practically we must conclude that their continued use must be necessarily fraught with harm in interfering with digestion, in arresting proper nutriment, in complicating secretions, and eventually in irritating the entire intestinal tract. Boracic and salicylic acids are no component parts of the system, and are neither needed nor tolerated as distinct food requisites.

"Besides, we know that under certain circumstances they are distinctly poisonous in their actions. Deaths have occurred from overdoses of both of these drugs, and why should not smaller quantities long continued have a like effect? The contractors are willing, however, to inflict these risks on the mere reports of some analytical chemists, who are seemingly paid in advance for favorable opinions regarding the actual healthfulness of these abominable adulterations. The chemist, expert as he may be in the processes of analyses, is not a proper judge of the physiological action of drugs. The clinician is the only one who can determine such points. It is the difference between theory and practice in the forming of proper conclusions. Doubtless when the reports are made by the surgeons who have had charge of the victimized men, it can be more properly determined what real harm this "embalmed beef" has occasioned.

Morally and scientifically any form of food adulteration is always wrong, and the sooner the guilty jobbers can learn this the better."

Does Your Head Ache?

Are your nerves weak? Can't you sleep well? Pain in your back? Lack energy? Appetite poor? Digestion bad? Boils or pimples? These are sure signs of poisoning.

From what poisons?

From poisons that are always found in constipated bowels.

If the contents of the bowels are not removed from the body each day, as nature intended, these poisonous substances are sure to be absorbed into the blood, always causing suffering and frequently causing severe disease.

There is a common sense cure.

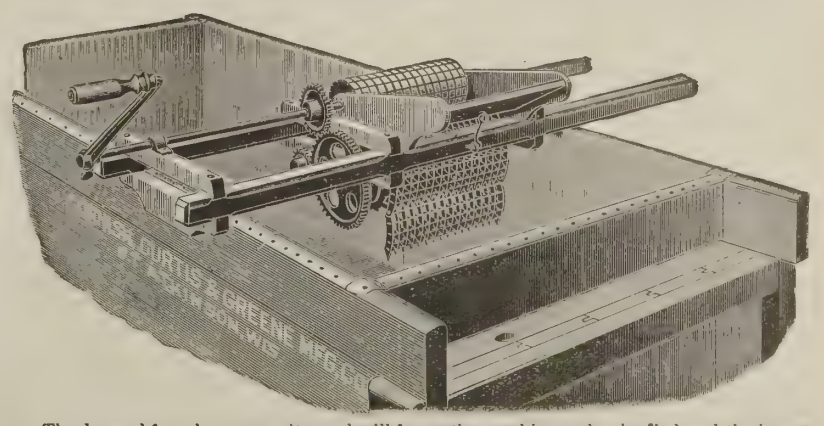
AYER'S PILLS

They daily insure an easy and natural movement of the bowels.

You will find that the use of

Ayer's Sarsaparilla

with the pills will hasten recovery. It cleanses the blood from all impurities and is a great tonic to the nerves.



Write the Doctor.

Kasper Rotary Curd Mill.

The demand for a large capacity curd mill for cutting curd into cubes has induced the inventor to bring out the Kasper Mill. In construction the mill consists of a rotary cylinder made of knives in the form of cubes. Against these knives a wooden roll revolves with indentations to fit the knives of the cylinder; the curd being fed into the hopper is forced through the openings in the cylinder by the wooden roll. The cylinder is made in three sections hung on hinges, and, as it revolves, each section as it comes to the lower part of the cylinder, opens and allows the curd to drop into the vat, the section closing again as the cylinder revolves.

It is estimated that the curd from 7,000 lbs. of milk can be cut in from 7 to 10 minutes. The mill operates easily, being light running and adjustable to either hand or belt power. Simplicity of construction, durability and ease of cleaning are some of its principal features. All parts being galvanized or tinned prevents rusting. Weight of the machine complete is about 38 pounds. List price, **$25.00.**

An Itemized Herd Report for Three Years.

A Model for Others to Adopt.

ED. HOARD'S DAIRYMAN:—In your valuable journal, I find useful suggestions and much valuable information.

Every dairyman should endeavor to secure the best possible results from his herd. To know whether he is doing this, he must not only keep an accurate account of his own herd, but be able to compare this with other herds.

As the success of the dairyman depends upon the results obtained from his entire herd, it should be his ambition to raise the standard of the whole. A record of a few of the best cows would be of little value for comparison, because it is only the products of the entire dairy that show whether the business is being run successfully or not.

Believing that an accurate record will be valuable for comparison with others, I send the record of my entire Cold Spring herd for the past three years. The record has been kept from the 4th of April of each year, and includes every cow that has been in the herd during the whole year. Animals sold or purchased during the year, have not been included, as the record of a cow for a few months only, but seldom shows what the product would be for the entire year.

The reports are in full detail. The milk has been accurately weighed and the amount of butter computed, by adding one-sixth to the amount of butter fat, as shown by the Babcock test, carefully taken the first of every month.

Following is the report of the three years: the next year, and, possibly, regain first place again the succeeding year.

As Mr. Olin well says, in a personal note accompanying the above, "correct reports of full herds are invaluable for purposes of comparison," and we join with him in the expression of a desire to see such reports from others. And this reminds us of the pertinent remark by Mr. Peer, who has recently visited the Island of Jersey, with commissions to purchase stock for several breeders in this country. Writing to the *Jersey Bulletin* he gives the phenominal records occasionally reported, the following notice:

I was present last week, at six Island parish shows; there were from 100 to 150 head of Jerseys at each exhibition, and not an inferior animal in all the number. I did not see a single animal but that was a credit to any breeder in any country. There are no thirty or forty pound cows on the Island, that anyone knows of, but I doubt if there is a state in the Union that can produce as many cows, that will average sixteen pounds, as can be found on the little Island of Jersey, seven miles wide and fourteen miles long.

Let no one misunderstand the DAIRYMAN'S position in this matter, which is, that no one knows what are the possibilities of a good cow, but anxious to know and declare "the truth, the whole truth, and nothing but the truth," we much regret that these reported yields of twenty-five or more pounds of butter in seven days are not confirmed by accurate tests of the milk, showing it to contain sufficient fat to produce the amount of butter claimed to have been obtained.

It will be seen that the average of milk and butter, during the past year, has, apparently, fallen off. But this is explained by the fact that fifteen of my extra good cows were sold in May of last year. I am satisfied that at no time has my herd been in as good condition as to-day.

To allow no deterioration, but constantly to increase the yield of his herd, should be the aim of every dairyman. M. H. OLIN.

Perry, N. Y.

There is litt'e that can be added to the foregoing, except to thank Mr. Olin for furnishing us this valuable matter for publication. The fluctations in the yield of the cows, which have been in the herd continuously, show that for reasons which cannot be fully explained, cows are, like men, not always at their best, and the one at the head in any given year, may fall back several numbers

How to Destroy Charlock—Interesting Experiments.

A large gathering of farmers and others—interested in the destruction of charlock so well known throughout Ireland as Preshaugh—attended to witness an interesting demonstration at the College of Agriculture, Uckfield, Sussex, on Wednesday last week. The demonstration was organized by Professor Malden, in conjunction with Mr. Strawson, who was present with a complete set of his horse and manual spraying machines.

There was a very representative attendance of local agriculturists, and among the strangers present we noticed Mr. E. M. Archdale, M. P, for the county Fermanagh. In order to afford the visitors an opportunity of seeing the effects of the different solutions, Professor Malden had a number of plots sprayed with dressings of various strengths a week before the date of the demonstration. The dressings applied varied from 1 to 4 per cent. of sulphate of copper, and from 3 to 7½ per cent of sulphate of iron.

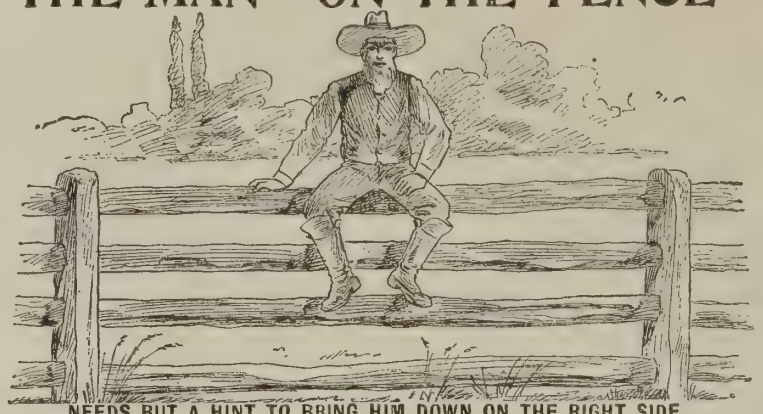
The Principal of the College, Mr. W. J. Malden, conducted the visitors round the plots and pointed out the effect of the dressings on the crops and on the weed. Most striking results were obtained. It should be stated that the solutions had been applied by the Twin spray, which had made excellent work for a hand sprayer; though when comparing the spray made by these and the horse sprayers the superiority and the regularity of the horse machines was very noticeable.

There was marked unanimity among those present as to the thoroughness of the effect of the dressings; and the sincerity of their expressions was emphasized by the large number of machines ordered. Perhaps the greatest compliment paid to the efficacy of the process was made by one or two who suggested that the weed had been pulled up, so totally had it disappeared. It may be explained that throughout the plots, whether on oats, tares or beans, the plots were divided by slips of unsprayed to show the effects of the dressing by comparison.

Eight plots were sprayed in the case of the tares. Where 50 gallons of 2 per cent solution were applied to early spring tares, the rows of which were almost lost in the charlock, the charlock was cleared out, except where one plant had covered up a smaller one; and the tares showed up clearly in the rows, making altogether a thoroughly good piece. Very noticeable was a plot of tares, a very little above ground in which the charlock was quite young, being little beyond the butterfly leaf. A 2 per cent solution had cleared the charlock and left the tares intact

Twelve plots of oats were sprayed. The first lesson learned in regard to these was that where there is a crop—in this instance about four or five inches high—a twenty-five gallon dressing, although useful, is not sufficient to destroy the charlock; also that a fifty gallon dressing, although weak, cleared the land of the pest; and furthermore, that a 2 per cent solution of sulphate of copper was practically as effective on the charlock as a 7½ per cent solution of sulphate of iron; while it in no way distressed the crop. There was a slight tingeing of the oat blade where the iron sulphate was used.

The most striking feature of this section of the demonstration was the excellent effect of a 1 per cent solution of sulphate of copper applied at the rate of 50 gallons per acre. It fell very little short in its effect on the charlock and was absolutely unnoticeable on the oats. A general concensus of opinion was that in crops at this stage a 2 per cent solution at 50 gallons, followed by 50 gallons at 1 per cent in about a week, would absolutely destroy the weed no matter how thick it stood, or a harrowing might be substituted for the second spraying.



In either case, the following up of the work when the weed was in an enfeebled condition would destroy all, without injury to the crop. It is obvious that where the weed is so thick that the small plants are covered by the big occasional plants, they will not get enough to kill them. Even with this the plants left behind were so few that they could be pulled by hand at small cost.

The beans experimented upon were on a neighboring farm and were practically enveloped in charlock. Very heavy dressings were applied, as much as 75 gallons of 3 per cent solution of sulphate of copper, and 75 gallons of 1 per cent sulphate of iron, with the result that the flat leaved beans were strongly tinged. The charlock was very much affected. In the case of the beans, as well as in the case of the oats and tares, the plots will be left to see ultimate effects.

Altogether, previous favorable reports of the operation were quite confirmed, and a most instructive set of experiments instituted. The many visitors were much interested in the grass and other experiments in progress on the college farm, and the experimental fruit garden was also much admired.

When a solution is stated to be 2 per cent, it implies that 2 lbs. of the sulphate are dissolved in 10 gallons of water. A gallon of water weighs 10 pounds; therefore 10 gallons weigh 100 pounds. Where 4 pounds are applied to 10 gallons (or 100 pounds of water) it is called a 4 per cent solution, and so on. —*Farmer's Gazette, Ireland.*

THE MAN "ON THE FENCE"

NEEDS BUT A HINT TO BRING HIM DOWN ON THE RIGHT SIDE.

He wants to buy a binder. Has been fooled once or twice and now really wants to know what machine can be relied upon—what machine will actually "live up" to the claims made for it by its makers. Here are some hints:

50,000 more Deering machines were sold last season than in any previous year.

6700 employes are working day and night in the Deering factories.

85 acres of ground are covered by the Deering factories—twice as large as any other in existence.

Deering machines have the only perfect ball and roller bearings.

Deering machines are the lightest draft grain and grass cutters ever built.

These are straws. They tell which way the wind blows. They should be helpful hints to the man on the fence.

DEERING HARVESTER CO., - - CHICAGO.

To Exhibit at Paris.

Improvements in H. B. Gurler's Dairy to be Shown.

H. B. Gurler, of DeKalb, Ill., has been complimented by a request to exhibit at the Paris Exposition, pictures showing new features in the construction of his famous dairy barn and other dairy buildings, and also to exhibit some of the appliances which he originated.

Mr. Gurler has the model dairy farm of this country and for advanced ideas and completeness of arrangement he is probably not excelled by any dairy in the world. His effort is to produce milk "as nearly ideal as possible," and he is doing that very thing. In the construction of his new dairy barn, completed some months ago, are worked out new and original ideas and in the request to Mr. Gurler it is proposed that the construction of the barn be shown in detail by means of photographs.

The contrivance by which the layer of absorbent cotton is held into the strainer, through which the milk passes from the cow into the milk pails, is a feature original with Mr. Gurler, and there are other new ideas in connection with bottling the milk which it is proposed to exhibit.—*Chicago Produce.*

Preserves

—fruits, jellies, pickles or catsup are more easily, more quickly, more healthfully sealed with Refined Paraffine Wax than by any other method. Dozens of other uses will be found for

Refined Paraffine Wax

in every household. It is clean, tasteless and odorless—air, water and acid proof. Get a pound cake of it with a list of its many uses from your druggist or grocer. Sold everywhere. Made by STANDARD OIL CO.

Self Sucking Cows.

W. K. Palmer of Kansas, writes the *Breeder's Gazette* giving his experience on this matter as follows:

I have a fine dairy cow, and, through neglect on my part, she began sucking herself. I tried everything to stop her, but did not succeed. As a last resort I took a horse collar and put it on her neck and she never sucked herself since. It does not bother her in fighting flies."

The Soy Bean.

The soy bean is an erect growing plant 1½ to 3½ feet in height, with stiff stem, having branches thickly covered with pods. Cold weather hinders its growth, and for this reason it is not best to plant until the middle of May, and if the rainfall is sufficient a planting may be made as late as July 1st. The ground should be in good tilth, and the weeds thoroughly killed, just before planting. Plant in drills, the rows 32 to 42 inches apart, dropping seeds two inches apart in the row. One-half bushel of seed per acre is required Cultivate as for corn, using small shovels on the cultivator, and being careful not to ridge the ground. When the pods turn brown, cut either with self rake reaper or with a common cultivator rigged up with two horizontal knives bolted to the inner shanks. Put the stalks in the cocks, where they should be kept until cured. Thrash with a common thrashing machine. Run slowly and use all blank concaves. The beans may be fed whole or ground.—*Kansas Station.*

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—The offering of butter on Monday's Elgin Board of Trade aggregated 16,140 pounds; 10,560 pounds were sold at 18 cents and 5,580 remained unsold with 18 cents bid. The market was reported firm at 18 cents.

The following sales were reported:

Factory.	*Pounds.*	*Price.*
Red Clover	4,500	18c.
Triumph	960	18c.
Big Foot	1,800	18c.
Spring Prairie	1,800	18c.
Dundee	1,500	18c.
Total	10,560	

The markets for the corresponding week of the three preceding years were as follows:

June 13, '98..34,800 lbs. of butter sold at 16c.
June 14, '97..24,780 " " " 14c.
June 15, '96..74,540 " " " 14½@15c.

The New York market Monday was reported firm at 18¾c. H. C. C.

Elgin, Ill., June 12, 1899.

THE name of the author of "How We Breed, Fe d and Handle our Cows," in this issue of the DAIRYMAN, was by mistake omitted from the article. It is T. A. Borman. Navarre, Kan.

DAIRY MARKETS.

ELGIN, Ill., June 12—Butter market firm at 18c, 11,000 lbs. sold.

CHICAGO, Ill., June 12—Butter—Creamery, extra, 18c; firsts, creameries, 16½@17c; seconds, 13½@14c; Dairies, selected, 15c; No. 1, 13@14c; No. 2, 12c; extra ladles, 12½c.

Eggs—Fresh at mark, cases returned, sold at 11c; loss off, cases returned, 12½c; duck eggs, 11c; goose eggs, 12½c.

Cheese—Full cream, Twins, new, good to choice, 7¾@8c; Young Americas, 7¾@8½c: Swiss 11@13½c; Limburger, 7@10c; Bricks, 7½@8¼c.

Cattle—The market opened strong to a shade higher, but later the advance was lost, and the market finished weak with some sales a shade lower than the close of last week. Exporters were among the principal buyers, largely at 5.15@5,30 for 1,240 to 1,450-lb. steers. Twenty-one head of 1,486 lb steers sold at 5.55, the top of the market. Strictly prime, 1,400 to 1,500-lb. steers would sell at about 5.60. The top a week ago was 5 50, and a year ago 5.20. Most of the 1,050 to 1,400 lb native steers sold at 4 85@5.25; corn-fed westerns, 4.60@5.30; distillery-fed steers, 1,064 to 1,324 lbs, 4 95@5,10; straight Texas steers, 905 to 1,076 lbs, 3.90@4 45; Texas cows and heifers, 3 40@3.65; native cows, 2,25@4 45; heifers, 3@5; distillery bulls, 1,230 to 1,385 lbs, 4 25@4.30; stags, 3 75@4 65; veal calves, 6@7 and feeding cattle, 3.75@4.65. Native butcher and canning stock ruled steady.

Bran—Quiet but steady, and sold at $10.87½ per ton.

MILWAUKEE, Wis, June 12—Butter—Creamery—Fancy prints per lb., 18c; extras, 18c; firsts, 16@17c; seconds, 14@15c; imitations, 14@15c. Dairy—Selections, per lb., 13@14c. Market unchanged and fairly active with receipts of 16,125 lbs. Arrivals affected by the heat have to be sold accordingly.

Cheese—American full cream—New, choice to fancy 8@8¼c. Brick—New, choice 7½@8c. Limburger, choice, 9@9½c; new, choice, 7@7½c. Swiss—Drum—choice, 12½@13c; block, choice, 10½@11c.

Eggs—Fresh, per doz., 11½@12c; loss off, cases returned Market unchanged and trade fair; receipts 592 cases.

FOND DU LAC, Wis., June 12—Offerings: 650 Twins and 500 Daisies; market firm, with sales of Twins at 7⅛@7⅝c.

PLYMOUTH, Wis., June 6—The sales reported to-day were 600 Twins at 7⅛c and 720 cases Young Americas, at 8c.

APPLETON, Wis., June 1—The offerings on the Appleton "call" board were 305 boxes Twins of which 110 sold on call at 7⅞c and 40 at 7¾c.

BERLIN, Wis, June 3—There were 491 boxes of Twins offered this afternoon. Selling prices, 7⅜@7¾c.

BRILLION, Wis, June 2—The sales reported on the Brillion board to-day were 341 cases Young Americas, 722 Twins and 925 Daisies at 7⅛c, 400 boxes Twins and Young Americas at 7⅝c.

HORTONVILLE, Wis., June 1—Offerings to-day were 142 Cheddars and 959 Twins. Sales 142 Cheddars at 7¾c; 216 Twins at 7⅝c. Ru'ing price, Cheddars, 7¾c, Twins 7⅝c. Market moderate.

SHEBOYGAN FALLS, Wis., June 7.—Fifteen factories were represented on the call board today and the offerings of 1,108 boxes were all sold to the highest bidder as follows: 175 cases of Young Americas at 8c; 656 at 8⅛c; 172 Twins at 7⅝c; 105 Daisies at 8c.

MANITOWOC, Wis., June 7.—Offerings of cheese at Dairy Board to day were: 100 boxes Twins, 400 boxes Daisies, 900 boxes Young Americas. Twins sold at 7⅛c; Young Americas at 7¾c; 225 boxes Daisies at 7⅛c; 175 at 7⅝c.

SHEBOYGAN, Wis, June 7.—Sales of the Sheboygan County Dairy Board; 535 Young Americas at 8c; 322 Twins at 7⅛c.

AVOCA, Wis, June 7.—On Board to day offerings were 1,254 boxes. Market firm at 7⅛@7⅜c. All sold.

KANSAS CITY, Mo., June 12—Butter—Creamery, 14½@16½c; dairy, 13c.
Eggs—11c.

BOSTON, Mass., June 12—Butter—Creamery, extra, 19c; western extra, 18½@19c; dairy extra, 17@17½c; imitation creamery, 15@15½c; western ladle 14c; print creamery, 19@20c; box creamery, 19@19½c.
Eggs—Fancy near by 17@18c; choice fresh, 15@16c; Michigan extra, 14½@15c; western, 14c; fair to good, 13@14c.

NEW YORK, June 12—Butter—Creamery Western extras, 18⅛@18¾c; do firsts, 17½@18¼c; state extras, 18¼@18½c; firsts, 17½@18.
Cheese—State full cream, large white, choice, 7¾c; colored, 7½c; small white, 7½c.
Eggs—State, Pennsylvania, and Western, 14½@15½c.

OGDENSBURG, N. Y., June 6—There were 20 lots, 1,610 boxes of cheese offered here Saturday. There were sales of 1,211 boxes at 8¼c, 314 at 8⅛c and 85 at 8 5-16c.

FULTON, N. Y., June 5—On the board to-day eighteen factories were represented with 1,750 boxes of cheese. Large sold at 7⅞c; small at 7⅜c. There was no b tt-r on the market.

UTICA, N. Y., June 5—There was the largest attendance on the Board of the season thus far. There was a decline in the sales, and a decline in the top price of large colored of ¾c. Large white cheese is pretty well cleaned up in this market The top price of 8¾c for small white was obtained for 317 boxes of "picnic" cheese. A lot of 76 boxes which brought 8c was of the same kind. The sales aggregated 82 lots, 5,323 boxes at 7⅞@8¾

The transactions on June 7, 1897, were 7,132 boxes with 7⅞c the ruling price. On June 6, 1898, were 8,336 boxes with the ruling price at 6½c. The butter market continued to show firmness, although prices were shaded slightly. The sales were ten 1-poond crates at 19c, 50 5 pound crates at 19c, 50 packages at 18c, 20 packages at 17c and 23 packages at 16½c.

CANTON, N. Y., June 5—On the board Saturday 2,054 boxes of cheese were offered. There were no sales of large reported, but small sold at 8½c. There were 1,387 packages of butter offered, with sales at 17¾c.

WATERTOWN, N. Y., June, 5—At the meeting of the Produce Exchange, Saturday, resolutions on the death of Robert McAdam were unanimously adopted. At the 5:30 call board 12 lots of cheese aggregating 725 large white were reported sold at 7⅛@7⅝c. The curb sales 69 lots, 4,850 boxes of large white at 7⅛c; 10 lots, 490 boxes of Twins at 7¾@7⅞c. There were only ten lots sold at 7¾c, the bulk of the large white cheese going at 7⅝c.

LITTLE FALLS, N. Y., June 5—With discouraging reports received here to-day from New York everybody was prepared to see lower prices. The sales are: 95 lots, 4,495 boxes, at 7¼@7¾c.
Butter—Very few sales of butter were made, all of it being dairy made, which went at 16@17c.

NEW YORK MARKET.

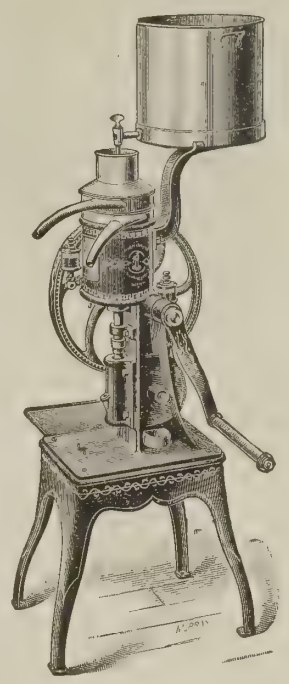
NEW YORK, June 10—Butter—Receipts for the week, 60,349 packages. Exports for the week, 1,367 packages.

Market this week ruled dull although prices were steady and slightly advanced at the close. Local trade only bought as they wanted and were critical in making their selections and paid 18¾@19c for extra creamery. There was a largs proportion of this week's arrivals made up of both crermery and ladle butter put into freezers on speculation this had a tendency to make finest grades rather scarce at the close and prices firm. New York State Dairy of fine quality is in very light receipt and wanted at 17@18c. Exports for the week averaging light and are mostly of cheap grades, mostly ladles at a cost of 13@14c, no encouragement being offered for the shipment of higher cost goods from American ports. We quote: Creamery, extra, 18¾c; medium, 17½@18c; poor, 15@16c. Dairy, extra, 17½@18c; medium, 16@16½c; poor, 13@15c.

Cheese—Receipts for the week, 40,632 boxes. Exports for the week, 13,929 boxes.

There was a good, cheerful, healthy market and stocks well sold up at the close, and prices firm, with a tendency to steady rates for next week. Sales in the interior yesterday were about as high as our market, lines of large sizes selling at 7¼@7⅜c and small at 7⅜c. Exporters bought liberally of finest full cream cheese at 7½@7¾c, and under grades at 6½@7¼c Small cheese found willing buyers at 7@7¾c. We quote:

Full cream, large, extra, 7⅝@7¾; medium, 7@7½c; poor, 6@6½c. Full cream, small, extra, 7⅝@7¾c; medium, 7¼@7½c; poor, 6@7c.



Eggs—Receipts for the week, 56,941 cases.

Most of the eggs arriving are showing the effects of the hot weather and all sales are made loss off. On strictly fancy stock prices are firm and demand good. We quote:

New York and Pennsylvania, per dozen, 15@15½c; western and northern, best marks, 13@14c; western and northern ordinary, 13@14c.

Print butter—Creamery, extra, 19c; firsts, 18c; seconds, 16@17c.
Eggs—Pennsylvania and nearby, 14½c; Western 14½@15c; Southwestern, 14½c; Southern, 13½c, loss off.

BALTIMORE MARKET.

BALTIMORE, June 8—Butter—The receipts of separator creamery this week have shown some increase in quantity and improvement in quality; to such an extent in point of fact are these two features noticeable, that the common expressions heard on the street and in the commission houses are that: "we are right in the height of the season", and "we will get no better quality than this", and "if you want to store any June's you had better begin now". The buyers, however, though they are not blind to the evidences of the "hereness" of the season, are apparently deaf to the invitations to stock up at current prices. The idea that of the general enhancement of values butter must partake has its advocates and adherents, but the grim fight that oleomargarine has waged against butter in the past remains in the memory of all and partially removes butter from the effect of the general improvement in values of commodities; and that this fight will be prolonged until Congress passes a law limiting the effect of the commerce clause of the Constitution with respect to oleomargarine is as sure as that night follows day. Therefore speculators here are paying more attention to other varieties, and we find the receipts of gathered cream creamery, imitation creamery and ladle packed taken on arrival if the color and flavor commend them. Receipts of store-packed are fair and demand active for all grades. Creamery separator, extras, 19@20c; firsts, 18c; seconds, 17c. Creamery gathered cream, extras, 18c; firsts, 17c; seconds, 16c. Creamery Ohio, extras, 18c; firsts, 17c: seconds 16c. Ohio storepacked, extras, 12c; firsts, 11½c; seconds, 11c. W. Va. storepacked, extras, 12c; firsts, 11½c; seconds, 11c. Creamery Blocks (2 lb.), extras, 21c; firsts, 20c; seconds, 19c. Creamery prints, (½ lb.), extras, 21c; firsts, 20c; seconds, 19c. Md., Va. & Penna. prints, extras, 19c; firsts, 18c; seconds, 16@17c.

Eggs—Receipts up to the present time have been about equal to the demand The trade is getting very choice in their selections; nothing but choice stock is wanted. So far there has been no accumulation of stock; market barely steady at 13c.

Cheese—Arrivals are composed entirely of new cheese. The supply is quite sufficient for all demands; market quiet and irregular. N. Y. state Cheddars, fine, 9¾@9¾c; choice, 9@9¼c; fair, 8¼@8¾c. Flats, fine, 9¾@9¾c; choice, 9c; fair, 8½c. Small, fine, 9¾@10c; choice, 9@9½c; fair, 8½c. Ohio—Flats, fine, 9@9½c; choice, 8c; fair, 7@8c. Ohio Picnic, fine, 9¼@9½c; choice, 9c; fair, 7¼@8c. Swiss cheese, fine, 13@13½c; choice, 10@11c; fair, 9@9½c.
501 Exchange Place. G. M. LAMB & BRO.

FOREIGN MARKETS.

BOSTON, June 10—Butter—Cable advices of this date from the principal markets of Great Britain to George A. Cochrane, give butter markets as very unsettled and almost near demoralization. The make is immense all over Europe. All continental markets are lower and the consequence is that English markets are simply flooded. There is no speculative feeling and a good portion of the receipts are going into cold storage simply because they are unsaleable at the moment. Quotations are hard to give and to a large extent are purely nominal. Finest Danish is to be had at 19@19¼c; finest Irish creamery 17@17½c, with fine factory 15½@16c. Canadian is arriving in increased quantities, and its landing condition being superior to Continental or Irish is taken at 17½@18c in boxes, but the trade is not at all active. American ladles not wanted at over 13@13½c, home makes are taken in preference by confectioners at the moment as they are to be had at 12@14c. Everything points to a dull trade for a month at least and there is little or no prospects of an improvement in prices.

Cheese—Cheese markets all tending downwards. All cheese cease to be a factor and what little is left is purely nominal. Trade generally is running on new cheese, which is arriving in increased quantities both from America and Canada. Sales this week have been made as low as 9@9½c with the trend of the market still downward. Chief quotations from America and Canada are lower, which makes buyers very cautious, who confine their purchases to immediate wants only.

READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

Wanted—An all around good farm hand to work by the month FRANK CRUMLETT, Box 276, Sleepy Eye, Minn.

Ensilage Cutter and 18 or 20 foot Elevator wanted. T. O. SANDY, Burkeville, Va.

Wanted—An honest and reliable man capable of managing a large dairy. Must be experienced in all dairy work and with all dairy machinery. Liberal wages to good man. G. C. STREET, Houston, Tex 18-4

Wanted—An all round man can find steady employment on a farm with a small herd of Jerseys. He must understand buttermaking, the use of a separator, and general farm work. Married man preferred. Address "X," care Hoard's Dairyman.

Scour Cure—Stops scours in calves. Large bottle $1.00. A. S. ALEXANDER, V. S., Evanston, Ill. 15-tf

Tamworths, ready to wean, $10 each, or $12.50 delivered. Hermanville Farm, P. E. I., Canada. 32-52

SOFT BACON.

The Canadians have been having trouble the past season with their bacon coming out of the salt in a soft condition. The market wants a firm, flaky bacon; "softness" causes great loss in value.

All sorts of reasons were given as the cause, and each one found believers.

Finally the Ontario Agricultural College took the matter up for close, painstaking experiment.

In these experiments the hogs are shipped directly to the factory, slaughtered, and the different groups packed separately in salt. When the bacon comes out of the salt it is carefully examined by experts, so that there can be no mistake as to its firmness or softness. The investigations are by no means complete, but some interesting results have been obtained. Full details of the experiments will be found in the College Report of 1898; but the following are some of the principal points brought out by the work up to date:

1. Though corn has been commonly blamed for producing soft bacon, it apparently has no evil effects when used for finishing hogs that have had plenty of exercise until they reach 100 pounds' live weight.

2. Neither does corn appear to cause softness when used for finishing hogs that have had no exercise, but have been fed skim milk with a mixed grain ration until they reach 100 pounds' live weight.

3. What has been said of corn may also apply to rape, when a two-thirds meal ration is fed with it.

4. Hogs confined in pens and fed wheat middlings during their early growth, and peas, barley and shorts during the finishing period (without either skim milk or whey), have a marked tendency to softness of fat.

5. Hogs given plenty of exercise, and fed as just described, produce firmer bacon than those confined in pens and fed the same ration.

6. The evil effects arising from lack of exercise can be overcome by the judicious feeding of whey or skim milk with the meal ration. From two to three pounds of whey or skim milk to a pound of meal will be satisfactory.

7. Whey and skim milk appear to have a greater influence than exercise in producing firm bacon.

8. Unthrifty hogs are more likely to produce soft bacon than growing, well-fed hogs.

The influence of whey and skim milk in these experiments was especially marked, not only in making rapid and economical gains, but also in producing a fine quality of bacon, in spite of lack of exercise. While corn produced firm bacon when used for finishing well-grown hogs, it must not be assumed that it will not cause softness when used under other conditions. Its influence on younger animals has yet to be tested. In Danish experiments corn was found to be decidedly injurious to firmness when fed to very young animals.

It is to be hoped that feeders of hogs will carefully study this question of producing firm bacon, for it is a matter of vital importance if we are to retain our profitable English trade.

Official Tests of Holstein-Friesian Cows from October 1, 1898, to January 1, 1899.

ED. HOARD'S DAIRYMAN:—These tests are for seven consecutive days and are supervised by officers of agricultural colleges and state experiment stations or by persons vouched for by such officers. The amounts of butter fat are determined by the Babcock test and the amounts of butter are calculated on the basis of 80 per cent fat to a pound of butter, the rule established at the World's Columbian Exposition.

Aaltje Posch 23176; age 8 years, 11 months, 5 days; amount of milk, 490.7 pounds; amount of butter, 23 pounds 8.3 ounces.

Calamity Jane 26292; age 7 years, 10 months, 11 days; amount of milk, 485.8 pounds; amount of butter, 22 pounds 5.2 ounces; in a food test, cost of butter per pound, 7.04 cents.

Calamity Jane 26292; age 7 years, 10 months, 11 days; amount of milk, 572.5 pounds; amount of butter, 25 pounds .9 ounces.

Columbus Girl's Beauty 15817; age 10 years, 6 months, 15 days; amount of milk, 404.2 pounds; amount of butter, 18 pounds

Daisy A. Mercedes 34298; age 5 years, 11 months, 11 days; amount of milk, 493.7 pounds; amount of butter, 19 pounds 7 ounces.

Fanny Rolph 47542; age 7 years, 6 months, 15 days; amount of milk, 481.1 pounds; amount of butter, 17 pounds, .5 ounces.

Ilzaida Zilla 35114; age 5 years, 8 months, 10 days; amount of milk, 453.3 pounds; amount of butter 18 pounds, 15.7 ounces.

Inka Hartog's Pietertje Kate 23484; age 8 years, 1 month; amount of milk, 456.8 pounds; amount of butter, 20 pounds 3.2 ounces.

Lady Pietertje Koningen 44026; age 6 years, 8 months, 10 days; amount of milk, 397.3 pounds; amount of butter 16 pounds 12 ounces.

Pleasant Valley Maid's Pietertje 18314; age 9 years, 3 months, 7 days; amount of milk, 542.3 pounds; amount of butter, 19 pounds 6.8 ounces.

Urica's Maid 27675; age 7 years, 10 months, 3 days; amount of milk, 354.5 pounds; amount of butter, 17 pounds .9 ounces.

Jetske Rue's Aggie 36514; age 4 years, 9 months, 17 days; amount of milk, 350.4 pounds; amount of butter, 17 pounds 1 ounce.

Alexina's Jewel Mechthilde 36046; age 4 years, 5 months, 25 days; amount of milk, 447.4 pounds; amount of butter, 20 pounds 15.7 ounces.

Zanca Wayne 36513; age 4 years, 1 month, 19 days; amount of milk, 317.3 pounds; amount of butter, 14 pounds 15 ounces.

Amarilla's Maid 38380; age 3 years, 8 months, 20 days; amount of milk, 361.6 pounds; amount of butter, 13 pounds 3 8 ounces.

Hartog DeKol 39496; age 3 years, 7 months, 28 days; amount of milk, 448.2 pounds; amount of butter, 18 pounds 5 2 ounces.

Superintendent Advanced Registry, Holstein-Friesian Association of America, Yorkville, N. Y.

THE NEW PENNSYLVANIA OLEOMARGARINE LAW.

The legislature of Pennsylvania enacted a new law last winter regulating the sale of oleomargarine, a distinctive feature of which, was that the product must not appear in the yellow color of butter, and that all dealers in the same must pay a special license fee. The law also regulates the sale of renovated or "process" butter. Dairy Commissioner Levi Wells has issued the following circular to all dealers in oleomargarine:

To Butter Dealers, Hotel, Restaurant and Boarding House Keepers, and others concerned.

Gentlemen:—Your attention is respectfully invited to the accompanying laws recently enacted governing the sale of oleomargarine, or butterine, and also relating to what has been commonly known as "boiled" or "process" butter. Licenses for the sale of uncolored oleomargarine or butterine will be ready to issue from this office on the first of June next, upon receipt of the prescribed fee.

All licenses expire on the 31st of December of each year, but can begin upon the first of any month by paying the proportionate amount for the time covered. For instance, from June 1, for a retail license, $58.33, this being seven-twelfths of the prescribed yearly fee. Signs to be hung in places of business, as authorized by the act, will be in readiness for distribution from this office by June 1, next

LEVI WELLS,
Dairy and Food Commissioner.

Trouble With The Night's Milk.

ED. HOARD'S DAIRYMAN:—We are shipping our milk to a nearby city. The morning's milk is cooled and kept in ice water and shipped at night.

The night's milk is run over a first-class cooler and aerator and cooled down to the proper temperature and shipped with the morning's milk.

The cows are stabled nights and fed a small grain ration twice a day. They run in good pasture by day, part of which is hillside, with a strip of lowland, but not swampy, in the same field; no standing water except in wet time. Cows watered from wells; know the water in wells to be all right. Have tried changing cows to entirely upland pasture; results the same. The milk is removed from the stable as soon as drawn. As far as I can see, the milk and cows are cared for in a first-class manner, from cow to consumer.

The sequel of the whole matter is that the morning's milk is all right and the night's milk all wrong, on account of a smell or scent (or in plain English, a stink) that is ruinous.

We have looked over the feeds very carefully and studied the problem to the best of our ability, but can reach no tangible conclusion.

SUBSCRIBER.

Palmyra, N. Y.

It is impossible to say what the cause is without more details of the conditions under which the milk is kept. Consequently the best we can do is to point out certain conditions which may cause your trouble.

In the first place, such troubles are almost invariably nearer home than the pasture. Feed will sometimes cause milk to have an odor or taste, but in such cases it is the result of a strong smelling plant, such as leeks, wild onions, etc., or is a bitter taste from eating weeds.

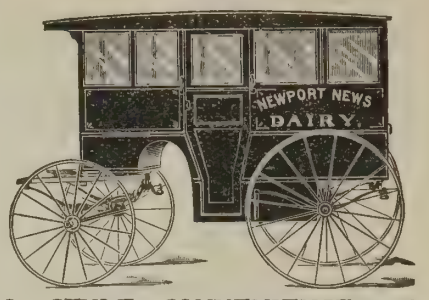
In no case will the taint be different from the flavor of the plant itself and is therefore readily recognized. It can be easily prevented by stopping the source of supply.

Tainted milk not due to food, comes from bacteria, or from the absorption of odors caused by bacteria.

The remedy in either case is to destroy the bacteria, by hunting out and removing the source.

In the first place, look to the source of your water supply. Your well may be all right, both to taste and smell, and yet contain enough infection from surface drainage to seriously taint the milk when the water is used to wash the milk vessels. Are you sure that there is no place where the cows can get mud on the udders? Are your milk cans allowed to stand when returned before being washed? Do you set the milk cans in a tank of water over night, and if so, is the water in the tank changed frequently?

Many other questions could be asked and the answers would indicate where the probable cause of the trouble might be found. Milk is extremely susceptible to taints of all kinds; it is a perfect food for almost all kinds of bacteria, bad as well as good. Nor are the malign bacteria any respectors of the desires of the dairyman to allow the proper class of bacteria to act in the milk. Constant watchfulness is the price of fine flavored milk as well as butter.



Oleomargarine in New York State.

ED. HOARD'S DAIRYMAN:—It has been a long time since I have written an article for an agricultural paper but happening to just look at the last number of HOARD'S DAIRYMAN I noticed that the oleo and food adulteration question was on deck again and haste to add this clipping from the *Albany Evening Journal* of April 12, 1899, as to the "beautifulness of oleo."

A certain commission dealer, whose name I might mention, but will not, is enjoying a great deal of quiet badinage and airy persiflage at the expense of his life-partner, these days. It all happened in this wise: The lady of the house is fond—O, so fond—of nice fresh-made dairy butter, "right off the farm," and she knows it when she sees and smells it, too, for wasn't she in the days long gone by, a farmer's daughter herself and didn't she "milk the cow with the crumpled horn," and agitate the old churn till the butter came to the top, and the ruddy glow of health to her cheeks? Well, I reckon.

So, when one morning, along about eleven o'clock, a nice, honest, horny-handed agriculturalist, with an occasional hayseed clinging to his whiskers, and portions of his broad acres still adhering to his farm made cow hides, drove up to the door and exhibited, with justifiable pride, a lovely, enticing layout of genuine cow product, "right off the farm;" mylady looked, smelled, tasted, then purchased a nice big crockfull, at a fancy

Pure Water

is as necessary as good feed. Don't make your stock drink out of old, dirty, rotten troughs. We manufacture **Galvanized Steel Tanks, Harness and Vehicles.** We have no agents. Our large FREE Catalogue tells how we sell direct from our Factory at lowest wholesale prices.

C. E. BANTA MFG. CO., Dept. 32 A, Chicago, Ill.

price—but surely it was worth it and more, it was so delicious.

"My dear, I have a nice little surprise for you"—this from mylady when pater familias came home to dinner that same evening.

"Indeed?"

"Yes, a large crock of lovely new dairy butter, right off the farm."

The dear, good woman thought papa would be pleased, and so he was until mama described the "farmer's" appearance somewhat minutely, whereupon he was cruel enough to remark:

"Why, my dear, that fellow is a well-known huckster from the South End, and you have bought a crock of oleomargarine, part of a lot I sold him myself, this morning!"

Hence the above-referred-to airy persiflage, which appears to greatly amuse papa, but almost makes mama wish she were dead.

Albany is the capitol of New York state and the residence of the commissioner of agriculture—the same man who recommended that the suit of the state of New York against Armour & Co. for a million or more for open violation of state laws, be discontinued for lack of evidence to convict, and upon Armours paying the state some $20,000 for expenses. And yet the political press of the state hold the commissioner up as a model official.

Moral—If dairymen and farmers want laws made or laws enforced they must not elect politicians to office. There is plenty of good material in the country.

Worchester, N. Y. OTSEGO.

A Successful Breeder, on Pig Raising.

In looking for a sire to improve my hogs, I selected the large Berkshire as having the good qualities I desired in a hog, namely: large litters of pigs and early maturity, and making fine hams, bacon and pork. In breeding, my aim is to have two litters a year, one in the first of March, and one the first of September. The spring pigs are fed and sold the last of September or first of October, and the fall pigs go into the April market. My aim in feeding is to make a pound of pork a day on each pig. Doing this and weighing the feed occasionally, I am able to determine when I am feeding at a loss. In describing my method of feeding, I expect to be criticised, and this is just what I want to show up my weak points, but as I have always had the best results by feeding this way, I still follow it.

The first thing we have to consider is the feeding and care of the brood sow. My sows run in the hog house which is double boards and paper between. In one end of the house is a door, and that is always open so the sows can run out in the yard. In opposite end, protected by partition, the sows have their bed, which is cleaned out once a week, and a large double box of straw provided. We put in enough so the sows can crawl in out of sight. Their feed is bran and shorts, equal parts, fed once a day, and corn once a day. I always have a few squash and beets and some small potatoes, which I feed also. The sows are provided with salt, ashes and charcoal.

Feb. 15th, or about three weeks before we expect the sows to farrow, we move them into the bank barn, where we have pens for them 5½x8 feet with fenders all around the pens, 8 inches from floor and 6 inches wide. The doors in these pens swing out and close the alley, so that the sow can run right into her pen. The sows are fed night and morning in the pens, and are turned out in the yard in the daytime.

Two days before I expect the sow to farrow, I shut her in her pen and give her about two bushels of short straw or chaff, and this is renewed every day till she farrows. After she farrows, I give warm water, and after 12 hours, I add a handful of feed and increase the feed gradually as the pigs need it. The third day I let the sow run out in the yard a few minutes and keep increasing time every day till the pigs are a week old, and then let them out, too. This is to give the pigs exercise, so they will not get too fat. As soon as the pigs begin to eat, I put a trough in an empty pen with a hole for the little pigs to get in. I commence by feeding a little warm skim milk, and after they have learned to take this, I add some shorts. In this it is necessary to be very careful and not feed too much and give the pigs the scours.

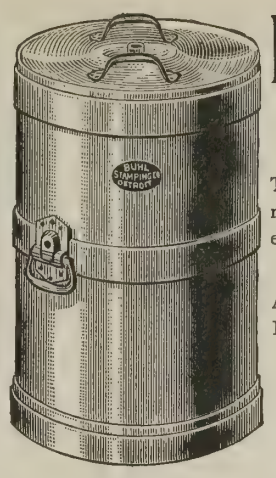
At the age of four weeks we castrate all the male pigs intended for pork. The pigs' bedding must be changed every day, and they must be kept dry. Increase the feed as they grow older, and at from nine to twelve week wean them. After this I feed some skim milk with shorts, corn and barley meal. The milk is fed first and then the meal is fed dry. I feed just enough so the pigs will clean the trough out, and would still eat a little more. This I do so the pigs will take plenty of exercise and not get off their feed.

The hogs run in the yard two or three hours in fine days in winter, and in summer have a clover pasture.

After the pigs are six months old and weigh about 200 pounds, I keep them in a large pen and do not let them out. I feed them all they will eat, corn meal with what skim milk I have. I give all the water they want once a day. At this time they will eat one-tenth as much charcoal as they will corn, and I am certain it adds nearly that much to the value of the corn.

As I don't want to make my hogs a ball of lard, I only feed heavy from 30 to 40 days, just enough to make the meat solid and firm. I sell my hogs to the local butchers and dress them myself. In keeping the hogs out of the mud and on a dry floor with plenty of dry straw I find they dress easier and look nicer when taken to market. —*W. J. Tingley, Minnesota, in the Dairy Reporter.*

Cleaning Test Bottles.



Mr. J. A. Conover, of the Manhattan (Kan.) Experiment Station sends the following hints on the proper cleaning of creamery glassware. He says:

"It very often happens that test bottles, pipettes and other articles of glassware in use about the dairy become coated on the inside with a white, and sometimes a brown, sediment, which is impossible to wash out with even the hottest water. This sediment not only gives the glassware a dirty appearance, but interferes with accurate measurements of milk or butter fat.

"In such cases a small amount of sulphuric acid will prove very helpful in cutting loose the white or brown sediment. Pour seventeen or eighteen cubic centimeters of acid in the test bottle, shake it up well and pour the acid into another bottle that needs cleaning. Rinse out the first bottle in hot water, and in nearly all cases it will be found to be nice and clear; if not, repeat the operation.

"Pipettes may be cleaned in a similar manner, care should be taken to get the acid all off of the upper end of the pipette, otherwise there will be danger of burning the mouth when the pipette is used.

"The burette used in Mann's acid test, often becomes so coated with white sediment, caused by the action of the alkali on the glass, that it is impossible to see the graduations. A little sulphuric acid poured into it, shaken up and then rinsed out with hot water, will leave it nice and clean."

BUHL CHEESE FACTORY CANS

Excel in Strength, Finish and Durability.

They will not leak or rust, are easy to clean, and keep the milk fresh and pure. The body sheets are the finest imported Cookley K Tinned Steel.

CAPACITY: 15, 20, 30, 40 and 50 Gallons.

AVOID IMITATIONS—All Genuine Buhl Railroad and Factory Cans are stamped with the Milk Can Trademark.

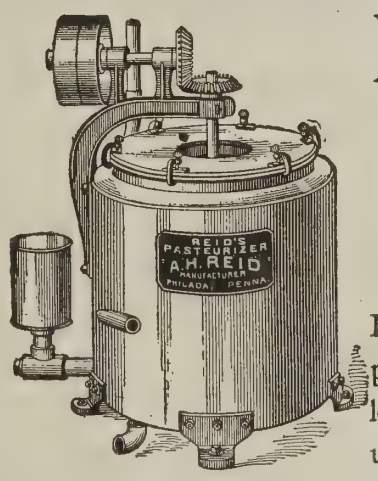
Gluten Feed.



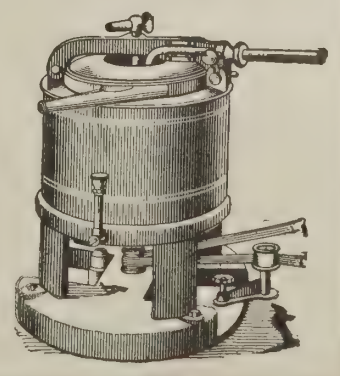
Any dairyman farmer who wants to produce milk at the least cost possible, cannot well afford to do without Gluten Feed. It increases the quantity; improves the quality, and lessens the cost of production.

It also keeps your cows in a strong and healthy condition.

Address Dairy Department,

The Glucose Sugar Refining Co.,

The Rookery, Chicago, Ills.



Do You Get Perfect Milk?

Do all your patrons bring absolutely perfect milk? If not, you can't get perfect results unless you have a pasteurizer. Pasteurization overcomes the effects of careless handling of milk and careless cleaning of cans and utensils. It removes all danger of bacteria, improves the quality of the cream and of the butter made from it and makes both keep longer.

THE REID Pasteurizer

affords the most scientific, most practical and economical means of pasteurizing whole milk, skim milk, or cream. Full information and the Reid Long Spindle Separator Book mailed free.

A. H. REID, 30th & Market Sts., PHILADELPHIA, PA. And CEDAR RAPIDS, IOWA.

Mr. Wheaton's Canadian Dairy Notes.

The Make of Spring Cheese. — Foreign Shipments.—Patrons and Quality of Milk. —Shipment of Process Butter.—Flavor of Dairy Products as Influenced by Water Supply.

ED. HOARD'S DIARYMAN:—About the most interesting feature in the dairy situation here just now is the very large make that is going on in the factories. From present indications it would appear that the month of June is likely to prove a record breaker, so far as the production of cheese and creamery butter is concerned.

The pastures are now in a luxuriant condition and able to furnish an abundance of good, succulent food for the production of milk. This is resulting in a large flow of milk and a largely increased supply at the factories.

This increased production is shown in the largely increased exports, since the opening of the season, as compared with last year. During May the total exports of cheese from Montreal were 85,183 boxes, as compared with 57,395 boxes for the same period in 1898, an increase of nearly 28,000 boxes.

There has also been a marked increase in the exports of creamery butter. For May the total shipments of creamery butter from Montreal were 15,102 packages, as compared with 7,141 packages for the same month last year, an increase of nearly 8,000 packages.

But the shipments of butter from New York for the same month were not as large as a year ago. The total was 4,234 packages, as compared with 6,028 packages for May 1898, a decrease of about 1,800 packages, making the net increase in shipments of butter from Montreal and New York, as compared with last year, 6,167 packages.

At this rate Canada is likely to go very far in advance of your country in her exports of creamery butter this season. She made considerable advancement last year, but her efforts this year promise to excel all others. Reports from New York show that prices there are too high to admit of an export trade being done at a profit.

The butter market assumed a stronger tone last week, on this side. As high as 16¾c is reported as having been paid at the factories for choice creamery butter for export. There is a larger demand reported for butter for the mining camps of the west for which fair prices are being paid.

The cheese market has a much easier tone than when we last wrote. The large increase in the make seems to be responsible for this. It is making buyers careful about what prices they pay for cheese for future delivery. Prices at the factories have dropped down to about 8 cents, though several lots were disposed of at considerably below this figure the latter end of the week, June 3rd. Though this is somewhat lower than was expected earlier in the season, yet it is about 1 cent higher per pound than was paid for the same class of goods last year at this time.

It may be that the market will strengthen as soon as June goods are offered. The cheese made during this month are usually of good quality, and are in demand for cold storage purposes. As many factories have very much improved their curing facilities, we may look for an improvement in quality of this month's make over that of last year.

When one considers everything, the good pasturage, the comparatively cool weather, the supply of good water, etc., there seems to be no good reason why June cheese should not be as fine in quality as the cheese of any other month in the year. The great drawback, to getting this fine quality, is the inadequate curing facilities which many factories have. Until these are improved, we are not sure of the quality of the product.

The patrons of a factory may supply the best of milk, and the maker may have that skill, intelligence and those good habits necessary for good work, and be able to make a first class quality of cheese, but if the goods, when taken out of the press, are placed in a curing room where the temperature will run up to 80 or 90 degrees, the best of results cannot be expected. For this reason it is necessary to keep "drumming" away till we get every factory in the land properly equipped with curing rooms in which the temperature can be controlled at all seasons of the year.

At the beginning of the season, when the outlook for cheese was so bright, it was expected that many more creameries than usual would give up butter making for cheese making, but the large make of butter that is now going on would seem to show differently. That our dairymen are wise in not giving up butter making for the other branch cannot be questioned. When, as we have so frequently pointed out, we have reached the limit of exports in regard to cheese, and when there is an almost unlimited field in which to develop our export butter trade, it would be a foolish piece of business to relinquish any of our efforts in regard to butter for any temporary gain there might be in cheese.

The stronger position of butter just now, as compared with that of cheese, will tend to convince those who have stuck to the former, that they have not lost anything in so doing. In the spring of the year, at least, the dairyman always stands to gain by making butter instead of cheese, as he can have the skim milk for feeding his calves. And if the ready cash is greater from cheese, he more than makes it up in the better quality of his calves.

One of our trade journals is responsible for the statement that a highly reputable United States firm has recently got itself into trouble through the shipment of a lot of 150 packages of finest ladle-packed butter, which the exporters say was carefully selected, and the order filled at 14 cents on this side of the water. They were greatly surprised to learn from the English firm, to whom the butter was shipped, that one of its customers, to whom a portion of it was sold, had been prosecuted and fined for selling it as a "pure butter", the analyst alleging that it contained 15 per cent of foreign substances. The English importers made a demand on the shippers for the amount of the fine and costs, with a request that future shipments be accompanied with a signed, written guarantee of purity.

While the American firm in question, may be in no way to blame for this fraudulent shipment, yet someone is guilty. It is hard to conceive that an ordinary creamery, even on your side of the line, would be guilty of palming off such "spurious" goods upon a reliable shipper, as a pure quality of butter; and yet it has been done, and it is the doing of this kind of thing that is ruining the export butter trade of the United States.

While it is exceedingly gratifying to know that we, in Canada, are not troubled with frauds of this character, yet we cannot help but sympathize with the legitimate butter maker across the line, who has to combat such frauds. We are glad to note, however, that your dairymen are bringing their influence to bear upon the state legislatures, and are securing laws for the proper regulation and sale of margarine, filled cheese, etc., and while it would be better to prevent the manufacture of these spurious goods in any form, yet a great work will have been accomplished if such laws are enacted, as will cause these articles to be sold for what they really are.

The Ontario Agricultural College has sent out a special bulletin to dairymen, announcing that the bacteriological department is ready to invesitgate any difficulties in the way of impure water, bad flavors, etc., at the factories, or bacterial infection of any kind. There can be no more important work than this done for our cheese factories and creameries. Makers frequently have difficulties in the way of bad flavors in the milk, cheese or butter, which, if placed in the hands of a skilled bacteriologist or chemist, valuable truths might be found out in addition to supplying means to remedy the difficulty. It is to be hoped that our dairymen will take advantage of Prof. Harrison's offer, as work of this nature will be of great value to the industry.

Prof. Robertson leaves for Great Britian about the middle of this month, in the interest of Canadian farm products, where it is expected that the good work accomplished last season by him, will be repeated. A few more years of such work will make Canadian food products known in every city, and shire town in the United Kingdom.

Prof. Roberson is at present visiting the government dairy stations in the northwest territories, where Mr. J. W. Mitchell has recently been appointed superintendent in place of J. A. Kinsella, who went to New Zealand as assistant to Mr. Ruddick, dairy commissioner for that colony. Mr. Mitchell has efficiently filled the position of instructor in the milk testing at the Provincial Dairy Schools, Guelph, during the past three winters, and will, no doubt, give a good account of himself in our great western country, where he has spent several summers as manager of one of the government dairy stations.

Toronto, Canada. J. W. WHEATON.

Barn Ventilation.

ED. HOARD'S DAIRYMAN:—I read in your paper of May 26th Prof. King's talk on ventilating barns and was very much interested. I have a basement barn 36x60 feet with cement floor, well lighted and warm but it is not properly ventilated. In very cold weather the siding is frosty.

The cows stand facing the outside of the barn, and no ventilation except the feeding holes. When it is very cold we have to keep them shut. The barn is framed with heavy timbers, only a low wall. There is a large ventilator on top of roof. I would like to know some cheap way of ventilating. I could put them in before filling the second floor with hay. How many shafts does it want and where located? P. A. S.

Madison Co., N. Y.

It will not be possible to give a very explicit answer to your correspondent "P. A. S." regarding the best method of providing ventilation for his stable, but some general directions may be given which will perhaps enable him to adapt them to his special needs.

I infer from his letter that the basement is largely of wood resting upon a stone wall, perhaps not more than 18 inches above the stable floor. If this is true, or if the wood work comes closer to the stable floor than this, it will probably be practicable for him to build a ventilating flue directly against

St. Lamberts AT PUBLIC SALE! COLUMBUS, O., JUNE 8, '99. Send for Catalogue. J. P. BRADBURY, . Pomeroy, Ohio.

Introduce Milking Jersey Stock INTO YOUR HERD. by buying one of our bull calves. Our herd of 325 has been bred for milk for 17 years. Best blood, size and constitution. Selected stock. **Large English Berkshires,** all ages, at their best. Write for our "little book", FILSTON FARM, Glencoe, Md.

High-Class JERSEYS The blood of Combination. (Sire of 25 in list) through Brown Bessie' (Champion Butter Cow at World's Fair), and Diploma 16219 sire of 48 in list including Merry Maiden Young Bulls, also cows and heifers bred to Recorder 29239-son of Brown Bessie. Printed pedigrees. State what is wanted. **H. C. TAYLOR, Orfordville, Wis.**

Hood Farm Jerseys **For Sale**—Bull with show ring and dairy qualities combined. Dropped Dec. 13, 1898, solid color, a show calf. Sire, Pedro Signal Landseer, son of young Pedro, sire of Eurotisama, 27 lbs 11½ oz. in 7 days 954 lbs 9 oz in one year and 11 others, son of Pedro. Dam, Lois Emerson, test, 18 lbs. from 298 lbs. 13 oz. milk; has averaged over 40 lbs. milk per day since calf was dropped; is a show cow. Write for price to HOOD FARM, Lowell, Mass.

We Have Sold SEVERAL OF **The A. J. C. C. COWS** advertised March 17th (see page 92), in fact, we quoted prices that made them desirable. There still remain some as well bred as those sold, which we think **genuine bargains.** We also have a few heifers that will be right to breed at time of turning out to grass. For cows, write for List No. 3, giving short pedigrees; for heifers, List No. 2. **WINTERGREEN HILL FARM CO., Scottsville, N. Y.**

For Sale . . . BULL CALF, Grand-son of the great Exile of St. Lambert 13657, sire of 72 tested daughters, "more than any other bull, living or dead." He is thrifty and good size; solid fawn color. His dam has a butter test of 15 lbs. 8¼ oz., in seven days. He will be sold cheap. **P. J. COGSWELL, Rochester, N. Y.**

Pure Bred **Tamworth Pigs,** Bacon curers choice. Pure Bred **Ayrshire Cattle,** largest imported herd in America. Stock all ages for sale. R. G. STEACY. Box 720 Brockville. Ont., Canada.

Write for what you want. Visitors always welcome. **JOHN E. ROBBINS, Greensburg, Ind.**

the wall of the barn at some convenient place on each side near the middle of the row of cattle. If it is desired not to carry the ventilating flue far out into the feed alley, and if it is not possible to set it back into the wall itself, it could be made in its lower portion narrow and long, say 6 or 8 inches in the clear inside, and 3 or 4 feet long so as to give a cross section of about 2 square feet. If it can be given a depth of 12 inches then a length of 2 feet would answer his needs, provided there were two of these flues, one on each side of the barn. This same proportion could be carried clear up to the plate of the upper story, or it could be made deeper and not so long after the upper story has been reached. The walls of these flues should be made as nearly air tight as possible, and if the siding of the barn above is open in its character, it would be well to face that side with a layer of 2 or 3 ply acid and water proof paper, tacking it directly to the side of the barn and then building the other three sides of the flue out of matched flooring, well seasoned. If your correspondent has a large cupola on top of the barn I think it would be unnecessary for him to carry the ventilators out through the roof, but let it go up to the plate, so as to make the flue as long as practicable.

In case your correspondent has long hay chutes reaching up through the bay next to the walls, it may be practicable for him to utilize one of these on each side as ventilating flue. The hay chute should, of course, be made with its walls air tight above the first, or stable floor, then in order to take air out from near the floor instead of at the ceiling, as is his practice, one method would be to make a flexible chute out of very heavy closely woven sail cloth or ducking, having the same shape as his hay chute and tacking it to the ceiling around the outer edges of the hay chute, making it in the form of a large sack open at top and bottom, and long enough to reach down within twelve or eighteen inches of the floor. It would probably be better to have the diameter of this six inches greater than the diameter of the hay chute, so that the hay would drop easily down through it, and so that it could be drawn off from the hay when it was desired to feed the cattle. This extension of the hay chute downward in the flexible form would allow him to move past it readily to draw it off from the hay and to swing it back against the wall and support it there out of the way of the cattle.

Unless the canvass is very tight it would be desirable to fill the pores in some way, possibly with a thin glue, containing a little flour or starch put on with a brush so as to make it more nearly air tight. Or it might be dipped in a thin grafting wax mixture. so as to fill the pores.

Your correspondent should make provisions for air to enter his stable at various places, and if he has double boarding this can probably be readily done, as suggested in my article in one of your recent issues, by making openings in the outer wall as low down as practicable and openings on the inside as close to the ceiling as possible. These openings need not be close to the floor level on the outside nor close to the ceiling on the inside, but the openings on the two sides should be not less than two and one-half to three feet apart, the inner opening being higher. If he provides four of these openings on each of the two sides, or three on each of the two sides and one on each of the two ends, giving them a cross section of about three inches by twelve inches, they will probably, with leakage of his walls about windows and doors, supply him with the requisite amount of fresh air. It is quite important to get the openings on the inside as close to the ceiling as possible in order that the cold air may be mingled with the warmest air of the stable before it reaches the cows. If he finds that too much air comes in through these openings, it will be a simple matter for him to provide a swinging or sliding lid to cover the openings, wholly or in part, and thus regulate the amount of air entering the stable. If he chooses, of course, he can go to the hardware store and get register faces with valves, which open and close for this purpose, but the other arrangement suggested would answer the needs at a less cost.

Dairy Work in the Maritime Provinces.

A Late Spring.—Roots for Dairy Feeding.—A Board of Trade for Prince Edward Island.—Cheese in Maritime Provinces.

ED. HOARD'S DAIRYMAN:—The rain has come at last, and watered the parched earth, yet a repetition of the last rain, of eighteen hours duration, would again be acceptable, for the ground is dry again, and pastures which have taken a start are now on a standstill.

The absence of rain this spring has greatly retarded dairy work in the Maritime Provinces. Milk is very scarce, and these factories which had begun cheese making are receiving very little milk. Not more than half the cheese factories of these provinces have yet begun operations. The majority of them will not start in before June the 20th this year.

Like the pastures, the outlook for the hay crop is discouraging. Farmers are, however, making the best of the abnormal conditions which now obtain, and have saved large quantities of peas, oats and vetches for summer feed. This season looks as if it would be a favorable year for the corn crop, for the corn could just as well be sown this year by the 20th of May—fully a week or ten days earlier than usual. The ground was then dry and quite warm, and in the very best condition for preparation. If our farmers and dairymen have not lived up to the privilege of sowing a large amount of corn this spring, they can only blame themselves if their cows dry up later on, for want of succulent feed.

A feature of the year is the large amount of mangels that are being sown. A few years ago, before the general dairy work prevailed, mangels were a *rara avis*. Turnips were the root crop and offered the succulence for the winter feeding of all our domestic animals. Now, that turnips have not been found suitable for feeding cows in milk, mangels and ensilage are fast displacing the turnip, and as only a very small percentage of the factory patrons yet have silos, the vast majority are growing mangels. Mangles, too, are found to be a splendid feed for swine in winter. Brood sows do finely on a ration of a half bushel mangels and a pound or two of oats, while if pulped and mixed with ground feed, they make a first-rate feed for fattening pigs.

An important meeting of dairymen takes place at Charlottetown on the 13th. The object of this meeting is to organize a Dairymen's Board of Trade for Prince Edward Island and making by-laws for same. One representative from each cheese and butter factory will have the right to vote at the meeting. Also any person who will pay one dollar into the funds of the Association. As special train arrangements have been made, a large representation and a successful outcome may safely be predicted.

Mr. Thomas J. Dillon, late dairy superintendent of Prince Edward Island, but now one of Canada's largest cheese buyers, has permanently located in Truro, Nova Scotia, where he will carry on business as a cheese buyer on an extensive scale. The isolated condition of the Island in winter, which afforded poor commercial advantages, was Mr. Dillon's reason for moving to Nova Scotia. Prince Edward Island is under deep obligation to Mr. Dillon, and the people are grateful, for they call him the "father of Prince Edward Island dairying." The great stride made by this small province in dairy work, and the excellence of the product, are due in the main to the energy and intelligence of Mr. Dillon.

Mr. Dillon, speaking a short time ago in New Brunswick, said, in substance:

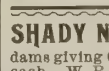
"In Prince Edward Island the farmers have, almost all, a money interest in their factories and largely on this account they are interested in sending good milk in order to increase their profits. The Island cheese has lately been commanding a higher price than the New Brunswick make. In the first place the factories over there are better built, most of them having sub-earth ducts, permitting a more complete control of temperature in the curing rooms."

In the early history of the Island cheese business, Professor Robertson brought down from Ontario a number of first-class experienced makers whose services had been very valuable. Mr. Dillon complains that there is not sufficient uniformity either in quality or size of the New Brunswick cheese. Island cheese are made either in thirty or seventy pounds in weight in fourteen and a half inch hoops.

Last year the milk netted the patrons 60 to 66 cents per hundred, and the majority of the factories pay by the Babcock test. A few add 2% to the fat readings.

Hermanville, P. E. I. J. A. M.

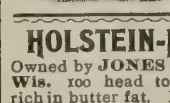
Look Out for Him.



Stockmen, farmers, liverymen, hotel proprietors and others are warned against a man sixty to sixty-five years of age, bald headed, blind in the left eye, about five feet ten inches in height, the upper rim of both ears off. He has gone by the name of Hart, Hinkle and Harman. His scheme to defraud is to pretend to be purchasing horses or cattle, usually dairy cows, claiming to have a dairy farm in the east, near New York city. He goes to a town and puts up at the hotel; then secures the privilege of some liveryman or stockman to receive his cattle. Then he hires a livery team, spends several days in riding over the country pretending he is buying cows or horses. He pretends that he is to have money sent him in a day or two, and that he is short, and borrows from $50 to $100, or whatever he can get to run him, pledging the cows he has pretended to buy. When he gets the money, he disappears to some other field of operations.

He talks with a slightly German accent, wears thick glasses, professes to have traveled extensively, and is an entertaining talker. He sometimes claims to have served in the navy and sometimes in the army. I caused his arrest in Jefferson, Iowa, took him to Kirksville, Mo., where he lay six months in jail. He was indicted and brought to trial during the May term of the Adair County Circuit Court. The jury was ready to sentence him, when the judge before whom the case was tried ordered them to return a verdict of not guilty, because of a mistake in the given name of the prosecutor. He escaped before he could be re-arrested, and when last heard from was going in the direction of Illinois, boasting that he intended to resume his business. This man has operated in the states of New York, Missouri, Ohio and Iowa, and probably other states.—*S. J. Miller in Breeders' Gazette.*

To Make Small Cheeses.



A ten-pound cheese may be made of fifty quarts of milk. Twenty-five may be the evening's milk, skimmed in the morning, to which is added the whole morning's milk. The milk is set in a heater on the stove, being stirred now and then, to heat slowly to 80 degrees, when the rennet is thoroughly mixed by stirring. Half a teaspoonful of the liquid extract for this quantity of milk, or a cake of the solid rennet, as sold in the stores, is enough. The milk is covered and set in a warm place until the curd breaks before the finger is passed through it. The whey is then dipped off and put in the boiler and heated to 150 degrees.

While this is doing the curd is broken by the hand, the hot whey is then poured on, and when the curd squeaks, when bitten, it is ready to be put into moulds and pressed down solidly and the whey is drained off. As soon as the cheese is solid enough it is taken from the mould and kept in a clean place and turned daily for a month. It should then be kept a month longer in an airy place, and the mould which gathers on it, scraped off once a week. A very good cheese may be made without this heating in hot whey.—*Indiana Farmer.*

HOLSTEIN CATTLE! The Choicest Milk and Butter Breed in the World. Write to Wis. Live Stock Ass'n, Appleton, Wis., U.S.A.

SHADY NOOK HERD Holstein-Friesians Two yearling bulls from dams giving 60 lbs. and 71 lbs. each. Test 4.5 and 3.6 each. W. R. GATES, Ripley, Jefferson Co., Wis.

Registered Holstein-Friesian Cattle. Best families of the breed. Aaggies, Waynes, De Kols, Netherlands, Pauline Pauls, Pietertjes. WM. O. JACKSON & SONS, South Bend, Ind.

GUERNSEYS! 84 Cows averaged 399 lbs. of Butter each in 1898. Some Choice Young Stock For Sale. ELLERSLIE STOCK FARM, Rhinecliff, N. Y.

AYRSHIRES Finely Bred and from the very best families. Stock for sale, bred for milk and butter qualities. Also fine herd Chester White Swine. Correspondence solicited. FRED TSCHUDY & SON, Monroe, Wis.

Preserving Eggs.

ED. HOARD'S DAIRYMAN:—Having received numerous inquiries from farmers during the past two months respecting the merits of "water glass" as a medium in which to keep eggs, we are led to think that certain conclusions drawn from an experiment, lately brought to a close, with this and other preservatives will be of interest to your readers.

The investigation was commenced last September, perfectly fresh eggs from the farm poultry house being used for the test, which consisted in immersing the eggs for varying lengths of time, from a few hours to six months, in (a) limewater, and (b) ten per cent solution of "water glass." Those eggs which were treated for a few hours, days or weeks, as the case might be, were subsequently placed, together with the untreated eggs to be used as a check, in a rack within a drawer in the laboratory, till the close of the experiment, March 30th, 1899. All the eggs were at a temperature from 65° to 72° F. throughout the trial.

The testing consisted in breaking the eggs into a glass and noting the appearance of the white and yolk, whether the yolk was stuck to the shell, size of air space, odor, etc. The eggs were then poached and again the odor, appearance, etc. noted. Without giving in detail the results of the various trials, it may suffice for present purposes to summarize the conclusions reached, as follows:

CONCLUSIONS.

1. In no instance, either of treated or untreated eggs, were any "bad"eggs found.

2. In all cases where the eggs were not kept covered throughout the period of the test with the preservative solution, shrinkage of the contents had taken place, as shown by the larger air space, the less globular form of the yolk, and in many instances by the adherence of the yolk to the shell. The eggs treated for seven days and less with lime water showed somewhat less shrinkage than those treated a similar length of time with silicate of soda.

3. It would appear that lime water and "water glass" used continuously are equally efficacious in preventing shrinkage. They may also be said to give practically the same results as regards both external and internal appearances, flavor, etc., of the eggs preserved. Since "water glass" (silicate of soda) is more costly and more disagreeable to use than lime water, we could not from the present results recommend the former as the better preservative.

4. The albumen or "white" in all the preserved eggs was very faintly yellow (though not to the same degree in all the eggs), the tint becoming deeper on boiling.

5. No offensive odor was to be perceived from any of the eggs when broken, but in all instances a faint but peculiar musty or stale odor and flavor developed on poaching

6. It is probable that no preservation will prevent the loss of flavor possessed by the fresh egg, but those which wholly exclude the air (and thus, at the same time, prevent shrinkage from evaporation) will be the most successful. Continuous submergence is evidently better than treatment for a few days.

"Water glass" known chemically as silicate of soda, is a fluid quoted at 60 cents per gallon. It is highly caustic, due to excess of soda, and consequently is more disagreeable to use than lime water.

The lime water may be made by putting 2 or 3 pounds of good, fresh lime in 5 gallons of water, stirring well at intervals, for a few hours, and then allowed to settle. The clear supernatant fluid can then be poured over the eggs, which have been previously placed in a crock or water-tight barrel. Some authorities recommend the addition of a pound or so of salt to the lime water, but the writers are of the opinion that this is unnecessary, and probably leads to the imparting of a limey flavor to the eggs by inducing an interchange of the fluids within and without the egg.

The all essential points to be remembered are: (1) That the eggs to be preserved shall be perfectly fresh, and (2) That they shall be covered with the preservative fluid.

Conclusion of the Matter.

How the Season of Ensilage Feeding Terminated.—Clover as Ensilage.—An Inquiry.

ED. HOARD'S DAIRYMAN:—When I wrote my article on experience with ensilage in the dairy, some time in April, the feeding season was not yet completed, and I wish to add a little here to what I then said.

As I then stated, the cows were doing exceedingly well and I was much pleased with the results obtained from the feeding of ensilage, as compared with a long experience with cured fodder corn.

Soon after this came the change from barn to pasture, when the cows need special attention to prevent any shrinkage in milk, as is sometimes the case before there is sufficient grass for a full ration and there is a a dimishing appetite for hay.

This year the weather being dry and ground hard, the cows were turned to pasture the first of May, quite early for this latitude, with the expectation of continuing the feeding at the barn as long as needed. But the cows soon showed they had no use for the hay, although of excellent quality. They, however, had a good appetite for the ensilage and daily feed of grain, and with these instead of there being any lessening in the yield of milk, there was soon an increase and the product of butter went decidedly ahead of anything experienced before, and this notwithstanding the weather was cool and dry, with short grass in the pasture. The cows reached the highest point of production by the middle of May, when eighteen—eight of which were heifers—averaged 10⅓ lbs. of butter in a week.

Of course, many dairymen will not consider this a very large yield, but it was at least 20 per cent more than made at any time previously, and doing pretty well for this part of the country.

The cows are full blood and grade Jerseys and a portion had been milked for several months. About 17 pounds of milk were required for one of butter. The cows had ensilage up to June in decreasing amounts, when most of them cared for it no longer. A small feed of grain is still given and may be continued through the summer.

From this experience in the change from barn to pasture, I consider ensilage of much value, and should be glad if we had a supply for use when the pastures begin to fail late in summer.

My son, who is the farmer, is confident that all things considered, we have got nearly or twice as much out of the corn crop put in the silo, as we formerly obtained from it as cured and fed dry.

Do you think, Mr. Editor, that it would be safe and advisable to put a quantity of clover into the silo at haying time, enough to last the cows until the corn is suitable to feed green, or better still, ready to put in the silo?

If this were the case, the silo would in this way answer a double purpose, with the advantage of having this feed at a time when most needed.

Would it require special pains to pack the clover, so as to keep?

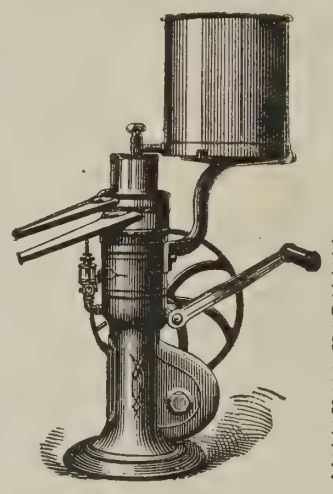
Last year we fed cured clover for a time with very good results, but quite likely as ensilage it would do better.

Franklin, Vt. E R. TOWLE.

Clover can be siloed, but if only a limited amount is put in silo, it should be well weighted and covered. Good, well cured clover hay cannot be much improved upon.

Hog Feeding.

Winter feeding of hogs is considerable of a problem, but Mr. Whaley has solved it to his own satisfaction. Having the dry and warm pen, the next consideration is to secure proper food in the cheapest way. The chief grain food is shorts, but sometimes a proportion of corn, peas and bran are also given. These are supplemented with pulped mangels and slops, such as whey, milk, and water when the other liquids are short. The pulped roots, shorts or chop and slop are mixed (about one bushel of shorts to two and a half of mangels) twenty-four hours before feeding, and given cold twice a day, except in very cold weather, when the mangels are boiled in a boiler standing in the feed room. The feed is not given very sloppy, except skim milk can be used, as too much water is injurious to the pigs. Mr. Whaley considers the only advantage of boiling is in having



The One Successful Color

IT gives entire satisfaction and is the only color that buttermakers should use. It is the one color found in over ninety per cent of the creameries of the country. Butter containing Wells, Richardson & Co.'s Color has the highest standing in the markets. . . .

THE

Wisconsin Curd Test.

It shows the quality of every patron's milk and points unerringly to the milk that causes Bad Flavor and Gass Cheese. For full particulars address

A. J. DECKER, Fond du Lac, Wis.

the feed warm in severe weather. At noon, pulped mangels are fed alone—just what is eaten readily. A change of feed is considered by Mr. Whaley very beneficial. A few ears of corn occasionally, and once or twice a week dry shorts are given with pulped mangels. A quantity of ashes, charcoal and sulphur are mixed in the regular feed about once a week. The litters are weaned when about seven weeks old, and are given shorts, mixed fairly thick with milk, twice a day for about a month. Mangels or sugar beets are then gradually added, and a few mangels are always given at noon.

Summer feeding is usually done in pasture lots, and Mr. Whaley is aiming to use clover for this purpose, especially for the growing pigs. Bran and shorts, mixed twenty-four hours ahead with whey, etc., is given in the form of a slop. The pigs are given full feeds of this twice a day, and the way they thrive is remarkable, not in putting on fat, but in growing the desirable strip of fat and strip of lean, bacon. When the market is down and expected to rise, the pigs are held back by less strong food, while their growth goes on apace. Mr. Whaley watches the feed market, and purchases his shorts and bran by the carload when the price is down

The following is a statement of Mr. Whaley's pig-feeding transactions in 1898:

ON HAND JAN. IST, 1898.

7 sows at $15	$105
1 boar at $15	15
8 shoats	65
10 shoats	58
11 shoats	45
13 shoats	30
10 shoats	15
Total	$333

Feed consumed in 1898:

21 tons 399 lbs. shorts	$278.85
500 lbs pea chop	5.50
1 861 lbs corn chop	16 75
5 tons 1,372 lbs. bran	65 41
800 bu. mangels	40.00
350 bu. corn in ear	55.00
Total value of feed	$461.51
Breeding stock purchased during year	23 50
Stock Jan. 1, 1898, as above	333.00
Total outlay	$818 01

Stock on hand, Jan. 1, 1899:

7 sows	$105 30	
1 boar	14.00	
4 boars	40 00	
10 shoats	68.00	
23 shoats	92.00	
11 shoats	33.00	
11 shoats	27.50	
10 shoats	15.00	
Total value of stock Jan. 1, '99.	$394 50	
		$ 394.50
Live pork sold in 1898, 17,366 lbs		805.38
Total assets		$1,199 88
Total outlay		818.01
Profit		$381 87

In concluding our interview, Mr. Whaley said: "There are four chief requirements in raising hogs for profit:

"1st. A good, high, convenient, well-ventilated, comfortable pen.

"2nd. Good stock of one or other of the popular breeds. The dams must be roomy and good mothers.

"3rd. Perhaps the most important is to keep the pigs clean, dry, and warm. We always clean all our pens every day throughout the winter, and let the pigs out into adjoining yards.

"4th. Give good attention, regular feeding with good food, and there will be found good profit in raising hogs."—*Farmers Advocate.*

Making Country Butter.

As to making butter in the country without ice, I say it can be done. Not tallow butter or axle grease, but butter of the gilt-edge variety, writes Mrs. Juliette Lamkin, of Texas. I know whereof I speak, and will give my own experience.

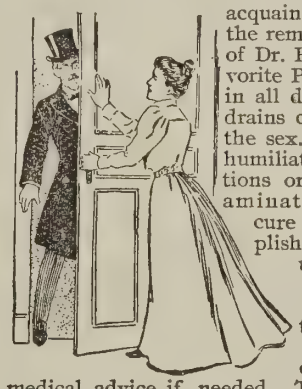
I live in the country where ice is an impossibility. Last summer I had no place to keep my milk and butter except on the north side of the room where the cook stove is kept. Every evening I skimmed the milk, twelve hours old, at the same time straining into the same jar some fresh strippings. The next morning I skimmed the milk of the previous evening and strained the fresh strippings into the jar already on hand; kept it cool as possible, and extremely hot days placed the jar into a tub of cold water from the well. Before dinner it was ready to churn.

By such management churning was an every day occurrence; and I will say, too, that when the cream was "ready to churn" the churning was done immediately, and the cream not allowed to turn to whey, or mold form on the top. Immediately on taking the butter from the churn, it was thoroughly washed with pure, cold water, salted, and the milk worked out as much as possible.

The butter through the summer was never white, tallowy, strong or musty. I sent it once a week ten miles to Dallas where I received the same paid for the best creamery butter. I sold it to private families, who said they preferred it to the creamery article, as it remained firm and did not get old soon and lasted longer. Two grocerymen in Dallas bought it several times for consumption in their own families.

When sending butter to market, I always cover it with wet cloths and pack it carefully in jars. Since the summer is gone and grass is dried up, and the cows are being fed bran, corn and products of the cotton seed, the butter is not so yellow and grainy, yet pure and wholesome and palatable. Sorghum fodder has a tendency toward making the butter yellow. I rather prefer summer made butter, and stoutly maintain that good butter can be made in the country throughout the summer without the use of ice, if the above plan is followed.

Three Essentials In Dairying.



We are frequently asked what are the more important points in dairying. While there are too many to be enumerated here, there are three things of which I want to speak briefly which are to me of great importance and on which our success as dairymen largely depend. These are breeding, feeding and care of the dairy stock.

Upon breeding depends altogether the quality of milk a cow will give, for be it remembered a cow has born in her the power to give rich or poor milk, and if poor, nothing that man can do will improve her in that line. But the quantity of milk a cow will give is determined by the one who has the care of her from the time she is born until she comes into dairy work, and depends almost exclusively on the feed and care given her. This word "care" means a great deal in the education of a dairy cow; it does not mean food and shelter alone; it means education, that we develop in the cow a love for us, or as it is usually expressed, affection. The more affectionate the cow the more valuable she is in the dairy. In our work we must remember that we have to do with the great law of maternity which induces a cow to give milk for her offspring.

She gives it in part, because of the affection she as a mother has for her young. The more of this mother love we have in the cow the better, but to develop and draw out this love, she must have kind treatment from her owner, from the time she is born until she goes out of the dairy. She must have a mother's treatment and a mother's care — M. E KING, in *Coleman's Rural World*

THE DOCTOR'S MISTAKE.

The doctor made a mistake in the number and called at the wrong house. No woman calls a doctor after she is once

acquainted with the remedial value of Dr. Pierce's Favorite Prescription in all diseases and drains common to the sex. Without humiliating questions or local examinations the cure is accomplished by the use of the "Favorite Prescription" supplemented by free medical advice if needed. This medicine is harmless in any condition of the system and can be taken without the slightest fear of bad consequences. It contains no whisky or alcohol. There is not an iota of anything narcotic in it. The relief it gives is permanent. In this it differs from many preparations which give temporary relief only by deadening the sense of feeling with narcotics, and the dangerous stimulants they contain create an appetite for strong drink. When a dealer offers a substitute for Dr. Pierce's Favorite Prescription, remember these facts.

When their diseases are deep-seated and of long standing, women will find it to their interest to write to Dr. R. V. Pierce, Buffalo, N. Y., who has had wonderful success in curing diseases of women. *He gives advice free*, and invites all to write him. Prompt, careful and personal attention is paid to each letter, and the fullest advice is always given.

"After five months of great suffering I write this for the benefit of other sufferers from the same affliction," says Mrs. H. A. Alsbrook, of Austin, Lonoke Co., Ark. "I doctored with our family physician without any good results, so my husband urged me to try Dr. Pierce's medicines—which I did, with wonderful results. I am completely cured. I took four bottles of Dr. Pierce's Favorite Prescription, four of his 'Golden Medical Discovery' and two vials of his 'Pleasant Pellets.'"

Does It Pay To Keep Cows Quiet?

A Bit of Practical Experience.

Should cows be kept quiet? Yes.
Why? Because it pays
How do you know it pays?

In answer to this question, let me relate the experience of one of our best dairymen. He says:

"I had heard a good deal about the bad effect of excitement upon the cow, and I made up my mind that I would know whether there was anything in it or whether it was like a good many other fine spun theories So one night I deliberately planned an attack upon my cows. I told the hired man to get him a cudgel, and I got one myself. We took the dog and went out into the cow yard just before milking. We halloed and yelled and flourished our sticks, but didn't strike a blow. The dog barked loudly, and for a time pandemonium prevailed. Then we let the cows into the barn and milked them.

"I was dumfounded at the result. The falling off in the amount of milk given was not so very much, though there was a marked difference; the most striking loss was in the quality of the milk. I have a reliable test myself, and know I cannot be mistaken when I say that at least two-fifths of the butter fat had disappeared—been burned up by the excitement of a few minutes' abuse just before milking.

"I told the hired man then that hereafter, if he felt as if he must strike somebody, to strike me, and that if he spoke at all in the stable I wanted it to be in a tone of voice such as he would use in speaking to me."

Now, this is not theory; it is not fancy; it is plain, matter-of-fact business. Every time a man kicks, pounds, shouts or otherwise has a "tantrum" with his cows he takes money out of his own pocket. He had better stand it if the cow thumps him now and then with her tail, or stands around a step or two while being milked, than to make a bigger fool of himself than the cow by getting into a rage and turning the stable into a bedlam.—*Practical Dairying.*

Sir J. B. Lawes, of England, has measured the amount of nitrogen that is washed out of soils by the fall rains. In one rainy season, there were 130 pounds lost from one acre in this way, during the month of September alone. During the hot weather of July and August, nitrification goes on rapidly in the soil. This means that nitrogen is changed from organic forms so that it is soluble in water. Most summer crops stop growing before frost.

There being no living plants to utilize this soluble nitrogen, the rains easily wash most of it out of the soil. September and October are two of the worst months for leaving the ground bare. When covered with Crimson clover or winter grain, the loss is much less, for these growing plants will utilize most of the nitrogen. Never let the ground remain bare during the fall and early winter.

COAL TAR BUTTER COLOR

Is prohibited by law in Austria as detrimental to the public health. Over one-half the butter in America is colored with coal tar dye. Do you want to know how to sell it? Send to us for the material for making the test and we will mail it to you free of charge.

The Holstein-Friesian Cow as an Economical Producer of Butter.

ED. HOARD'S DAIRYMAN:—In 1897, the Holstein-Friesian Association of America adopted a plan known as "Food Tests," and offered prizes for cows tested under the supervision of representatives of the different experiment stations, to determine the food cost of butter production. A schedule of prices of the different food stuffs was fixed, based upon recommendations of some of the leading experiment stations, and the yields of butter fat and food consumed by competing animals during the seven days tested were conducted and vouched for by experiment stations.

This step on the part of the Holstein-Friesian Association is certainly one in the right direction, as the value of any dairy cow is measured by the amount of milk and butter produced in return for amount of food consumed. The all important problem that confronts the dairyman today is the one of economical production and net profit over and above cost of production.

Believing that some data touching upon this point would be of interest to practical dairymen, I have formulated a table showing results of tests of Holstein-Friesian cows and heifers, competing for prizes in "Food Tests" last year. In this table I have credited these animals 25 cents for each pound of butter fat produced, and 20 cents for each 100 pounds of skim milk, taking 80% of the whole milk to determine the amount of skim product. This price of 20 cents per 100 pounds is based upon its feeding value as compared with other foods for growing young pigs and calves upon the farm, and has been found to be worth that, in feeding trials at some of the leading experiment stations.

NAME OF COW.	Class.	Days since last calf.	Dry matter consumed during test—pounds.	Average daily consumption of dry matter—pounds.	Total amount of butter fat produced—pounds	Average daily yield of butter fat—pounds.	Dry matter consumed for one lb butter fat—pounds	Yield of butter fat for 100 lbs. dry matter.
Helena Burke.....	Mature	81	153.93	21.99	13.47	1.92	11.42	8.75
Aaggie Grace 2d's Pietertje.....	"	87	154.48	22.09	13.21	1.88	11.68	8.56
Dutchess of Ormsby 3d.....	2 yr. old	77	122.93	17.56	11.01	1.57	11.17	8.95
Artis Tritomia Netherland.....	"	19	104.27	14.89	8.50	1.21	12 25	8.16

In the test for aged cows, Helena Burke was awarded first prize and Aggie Grace 2d's Pietertje second prize. It is but justice to the cows and the breed to say that prior to entering this test these two cows had been shown at five different state fairs, and had covered a distance by rail of over 2 500 miles. Notwithstanding this and the very trying conditions surrounding a fair ground test, this expenditure of dry matter on the part of these two cows to produce a pound of butter fat is not only remarkable but *phenomenal*, and surpasses any record I have ever seen reported upon this basis.

Totals.....	....	6,025.4	217.10	$20.27	.....	$54.27	$9.64	$63.91	$43.64

A summary of this table follows:

Seven mature cows average 15.15 pounds fat per week at a cost of $ 091 per pound.

Two four-year-old heifers average 14 64 pounds fat at a cost of $.127 per pound.

Three three-year-old heifers average 13.47 pounds fat at a cost of $.081 per pound.

Four two-year-old heifers average 10.31 pounds fat at a cost of $.086 per pound.

The entire list of sixteen cows and heifers, which includes every animal tested during the fiscal year ending in March, 1898, averaged 13 5 pounds fat at a food cost of $.093 per pound, and they return a net income, above food cost of production, of $43.64, or an average of $2.67 per cow.

Further study of this table shows the injustice of judging the dairy cow on a basis of food cost of butter fat alone. This will be seen by a comparison of the first cow on the list, whose butter fat was made for $.077 per pound, and Calamity Jane, who required $.115 for a pound of fat. The natural inference would be, that the first was the most profitable cow; such, however, is not the case, when we note the difference of net profit in the last column.

It will be farther noted, as a rule, that the cows giving the most milk, make the most fat and return a greater net profit. Not only is it true in these tests, but in the dairy tests at the World's Fair, the breeds taking the highest standing were those giving the most milk, and this seems also to apply to the different individuals of the different breeds.

These tests present a very creditable showing for the Holstein-Friesians, and the performance is one not easy of approach by rival breeds. It demonstrates very conclusively, the value of the Holstein-Fr'esian as a business cow from a practical standpoint; but to show still more evidence of the high standing of the breed, as economical producers, I present another table showing the results of tests of two cows and two two-year-old heifers, that were entered in the dairy test at the Trans-Mississippi Exposition held at Omaha. Unlike other fair ground tests, the prizes here were awarded on a basis of dry matter consumed to produce a pound of butter fat. It being a food test, impartial to any dairy breed, it was hoped it would prove a drawing card and that representatives of all the dairy breeds would be entered for competition. The Holsteins, however, were the only ones entered, and the other breeds "were conspicuous by their absence," a fact very much to be regretted.

In the test for aged cows, Helena Burke was awarded first prize and Aggie Grace 2d's Pietertje second prize. It is but justice to the cows and the breed to say that prior to entering this test these two cows had been shown at five different state fairs, and had covered a distance by rail of over 2 500 miles. Notwithstanding this and the very trying conditions surrounding a fair ground test, this expenditure of dry matter on the part of these two cows to produce a pound of butter fat is not only remarkable but *phenomenal*, and surpasses any record I have ever seen reported upon this basis.

In the class for two-year-old heifers, Duchess of Ormsby 3d was awarded first prize, the second going to Artis Tritomia Netherland. We find the amount of dry matter consumed to produce a pound of butter fat to range from 11.42 lbs. to 12.25 lbs., with these four animals. The economy of their work can, perhaps, be better appreciated when we consider (and I believe such is the finding of experiment stations in tests of this kind) that the expenditure of 18 or 20 lbs. dry matter to produce a pound of butter fat would be correctly interpreted as being very economical with the dairy cow, under the most favorable conditions and natural surroundings.

It must be remembered the results here mentioned are not based upon the statements of interested owners, but upon unquestionable authority, thus establishing the absolute accuracy of the records, and any dairyman studying the results of these tests from a practical, unprejudiced standpoint can but concede the outstanding merit of the Holstein-Friesian cow.

Her past is at least secure; her present can but command the attention of any dairyman desiring a machine for the purpose of economically converting food materials into milk and butter, and her future gives promise of a progressive march to a still higher pinnacle, as the work of improvement advances in the hands and under the management of the intelligent American breeder.

Rosendale, Wis. W. J. GILLETT.

Cow Peas.

June is the month for planting the pea crop. White peas of all kinds would do better planted earlier. But the colored stock peas are now in order. If you wish to plant after cutting the small grain, and have plenty of seed to sow broadcast, then a bushel or over may be used per acre. But as peas are scarce and high, it is better to drill them. Open rows two and a half feet apart, and drop half a dozen peas every twelve or fifteen inches, and you can plant an acre with a peck of seed.

If promptly plowed they will make a good yield of peas or vines. The crop can be greatly increased by using acid phosphate and kainit, mixed in the proportion of 200 pounds acid to 100 pounds kainit, and using 150 pounds per acre in the drill.

Plant as soon as the grain is cut, and plow out middles as soon as practicable. About two weeks later, plow them again. This will hasten the growth, and insure a good crop. They improve the soil almost as much this way as when sown broadcast. If the plowing has been done so as to leave the surface level, the mower may be used to cut for hay.

This is suggested as the result of several years' trial, and gives a chance to lessen the expense when the seed are high.

For planting with corn, we prefer to sow peas when we plow corn last time. Our reasons are, in part, that the peas do not then grow enough to interfere with the corn before the corn has about matured. Then they cover the land and soon make good vines and often a full crop of peas.

Planted early between, or by the side of the corn, they interfere somewhat with the clean cultivation of the corn, and in dry spells divide the water supply, and often run over the corn so as to break it down, and cause rotting, if the fall be a wet one.

But whether you plant in the corn row, or sow at laying-by time, or plant after stubble, be sure to plant a liberal area to peas.

Later we will discuss saving the hay. Now we wish to insist that in the rush and pressure of June work you do not fail to plant peas. And when they ripen, do not fail to gather plenty of seed for home use, at least.

Peas are rarely written about as a human food. They rank among the best upon the table through the summer season, and in winter the dried peas are nutritious and palatable. They are almost meat and bread both. To the laborer and the soldier they give strength and endurance.—*Southern Cultivator.*

Silage Without a Silo.

Information Wanted.

ED. HOARD'S DAIRYMAN:—I am much obliged to you for forwarding me F. W. Woll's book on silage, which I find exceedingly interesting, especially as I purpose putting up a silo myself. There is, at present, only one silo in Jamaica and that was made of solid concrete, quite regardless of all expense. I do not care to lay out so much money for a concrete silo, and wood is very expensive on account of heavy freight and duty. I should like to try one of Blunt's Silo Stacks, either round form or square form, as mentioned in F. W. Woll's book on silage, pages 80-83. I should be much obliged if you would kindly let me know where I can get such a silage press and what the cost of it would be. At the same time I should be glad if you would let me know what experience you have had with these silage presses. You must bear in mind that, as I said before, lumber is very expensive out here, from $25 to $30 per thousand, and besides, our carpenters, never having heard of a silo, would be likely to make a mess of building a wooden silo, and a stone or concrete silo would be also expensive.

For these reasons I should like to try a Blunt's silo press, but don't know where to get it from and shall be much obliged to you for the information.

Apologizing for the trouble I am putting you to and thanking you in anticipation, I am,

H. FARQUHARSON.

Montego Bay, Jamaica.

We much regret our inability to give the information requested. The fact that lumber is not so expensive in the United States and Canada has made it unnecessary to investigate the problem of making silage without a silo. If any of our readers can supply the information desired, we trust they will do so at once.

Meantime we do not have much hesitancy in expressing the opinion that it would take but a year or two at most to save enough, with a good silo, to more than meet the extra expense of building a good stave silo. And it would not require any experience or very much skill to construct one in accordance with the illustrations and directions published on page 267. The main point would be to see that the edges of the staves were made perfectly straight.

It would require somewhat less than 3,000 feet of lumber to build a silo 16 feet in diameter and 24 feet deep, and such a structure would hold approximately 90 (short) tons of silage, sufficient to allow 30 pounds daily to 30 cows for 200 days.

A Tennessee Ration.

ED. HOARD'S DAIRYMAN:—Enclosed you will find $1.00 for subscription to the DAIRYMAN. When my subscription expired last March, I was receiving three agricultural weeklies, two of which were sent me for an occasional item of news, but none of them supplies the place of the DAIRYMAN, and I find I must have it again.

Will you formulate me a ration for a herd of cows that will average about 900 pounds? We have, on the farm, plenty of fine blue grass and Japanese clover, corn, corn stover and pea hay. We crush our corn, cob and husk. We can buy wheat bran at $10 and cotton seed meal at $19, delivered.

Verona, Tenn. W. M. R.

Our friend's experience is very much like that of many others, who try, from time to time, to dispense with the weekly visits of the DAIRYMAN. It is not too much to say that more frequently than the constant reader realizes, this paper proves itself to be a friend in need. Apart from everything written for its columns by the editors, the contributed articles, and the carefully selected matter drawn from home and foreign papers, experiment station bulletins and other publications, furnish a good ration for the intellectual development of the man who wants to be a progressive and prosperous dairyman. We do not pretend to furnish an aggregation of fixed rules, or set forth opinions with the assurance of the weather prophet, who predicts storms and calms for specific days twelve months in advance, but do claim that nowhere else are the principles and ex-

AT AUCTION!

THE FINEST

Stock and Dairy Farm

IN THE WORLD.

THE CHANCE OF A LIFETIME!

To close the estate of the late Hon Theo. G. Bennett, his magnificent farm with its celebrated **Stone Buildings** will be sold to the highest bidder **FRIDAY, JUNE 30th, 1899.** It may go very cheap. If interested, send for descriptive circular. **F. D. BENNETT,** Administrator, Jackson, Mich.

Impossible for any **Liquid** that is **Sprayed** on **Cow,** to protect her from **Flies,** in sun of 100 degrees ¼ as long as **"SHOO-FLY"** applied with a brush. See "Shoo-Fly" adv. page 361, this paper.

THE DROWN

Patent Cow Stall

Guarantees PERFECT COMFORT to the Cow and Cleanliness of Milk.

This gives GREATEST ECONOMY OF FOOD.

NO TIES.

It costs more to not have than to have it. Send for information to H. C. DRAKE or M. J. DROWN, Madison, Wis., for Wisconsin; other states, M. J. DROWN.

Mention HOARD'S DAIRYMAN when writing.

perience of dairying so fully, or so intelligently discussed, as in these columns.

In the matter of formula for ration we suggest as follows:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
7 lbs. blue grass hay	5.44	.34	3.28	.07
7 lbs. clover	5.93	.48	2.51	.12
7 lbs. corn stover	4.16	.12	2.27	.05
3 lbs. bran	2 64	.38	1.16	.09
3 lbs. corn	2.07	.18	1.80	.10
2 lbs cotton seed meal	1.84	.74	.33	.24
Totals	22.08	2 24	11.35	.67

Pea hay may be substituted for the clover; and in regard to the latter we have to say that having no analysis of the specific variety named, we have assumed, on the authorty of the Mississippi station, that it is equal to common red clover.

Caring for Whey.

The proper method of caring for the whey:

First: Place the whey tank under cover.

Secondly: Have it so arranged that it can be cleaned daily.

Thirdly: The whey should be heated to 160° F.

In placing the whey tank under cover, it is protected from dirt and rain. I found it a good plan to keep the whey tank in the engine room.

The tank, which contains the whey, should be so arranged that it can be easily cleaned each day just as the vats in the make room are cleaned. It is only a few minutes work to wash this tank each day and there is no reason why this tank should not be kept as clean as the milk vats.

When whey is cooked to 160° F. it remains quite sweet for 24 hours; of course there is some acid in it, but not enough to injure it for feeding purposes. The whey can be cooked with live steam, beginning as soon as possible after the whey is in the tank, for the longer the whey stands before it is heated to 160° F. the more acid will be developed. When whey is handled in this way it makes good feed for any kind of animals. In feeding it to calves there should be a small amount of linseed meal mixed with it. The linseed meal to a certain extent takes the place of the casein which has been removed from the milk, for the linseed meal is very rich in protein matter.

The expense of caring for the whey in this way is very small and the results are very gratifying, both to the farmer and the cheese maker.

In the first place the farmers will have good wholesome whey to feed to their stock, and secondly, the cheese maker will have no gas forming bacteria coming from his whey tank. Consequently if the whey is properly cared for, the farmer will have better stock and the cheese maker better cheese.—*Dairy Reporter.*

CONCERNING OUR ADVERTISERS.

IT WORKS LIKE A GRAIN BINDER.

The only way to bind corn is the reasonable, sensible, *horizontal* way; that is, as nearly after the principle of a grain binder as is possible. Those who have used the Deering Horizontal Corn Binder know that binding corn by machinery is no longer an experiment. This machine has roller and ball bearings, it is light for two horses and free from side draft, and it does not scatter loose ears all over the field.

Someone will probably get a great bargain at the auction sale of the Bennett farm, and a hundred others will regret the lost opportunity. See notice in another colnmn.

Those who are desirous of obtaining a good pumping plant for farm and dairy purposes, should address the American Well Works, of Aurora, Ill., who are building a horizontal self contained gasoline engine for well pumping purposes complete, ready to screw to the well pipe.

Jos. Condell & Sons, breeders of Herefords, Chicago Heights, Ill., write Dr. A. S. Alexander, V. S., Evanston, Ill., as follows:

"We have used your scour cure, and it does all you claim it to do. We used three doses on a calf that had bloody flux, and two doses for a calf with scours It cured in both cases, leaving no bad results." See advertisement page 361.

VETERINARY.

Queries in this department answered by WM. HORNE, M. D. V. S., Janesville, Wis.

COW PHYSIC—Three-fourths to 1¼ pounds Epsom Salts (according to age and size of animals) and two ounces of best ground ginger. Pour over this three pints of boiling water. When at 105° F., give gradually as one dose.

CALVES WITH COUGH.

I have nine calves that have a bad cough; have had it for about three weeks and are growing worse. This evening, one is quite weak. Most of them have the scours some, but all eat well and drink well. They are about six weeks old. Might it be the cold, damp weather that would cause the cough?

Pierson, Iowa. D. T. D.

ANSWER.

Most certainly the cold, damp weather has all to do with cough, etc. Feed of the best and most nutritious food in plenty. Each morning give each calf, gelsium ten drops; lobelia, one teaspoonful; old whiskey, one tablespoonful; soft water, 1½ tablespoonfuls. Give this very gradually; allow it to trickle over the larynx, etc. Give for three mornings, then wait a day; then repeat just twice; then wait two days; then give one dose every third day for four doses.

POOR FLOW OF MILK.

I have a grade Short-horn that freshened Jan. 24th, and now gives about thirty pounds of milk—on pasture and a feed of rye at night, with a little ground feed (oats and corn) mornings—where she ought to give about forty pounds of milk. She eats fairly well, and looks all right. Her bowels are very loose. I gave her a dose of physic this evening. What else can I do? Was that right? R. H. D.

Corydon, Pa.

ANSWER.

There is nothing to do. There is nothing to need doing anything for. All cows are liable, at any time, to drop off in milk. Sometimes a cow freakishly increases her milk. Let her alone. There never is any danger in a dose of physic, excepting to a weak subject, or in a case of acute inflammation.

INJURY TO LEG.

One of my horses jumped over the wire fence, three years ago, and hurt it in the hind leg. She got five little points in it. The wire fence was rusted. She don't go lame but the leg swells up while standing in the stable, but when working it grows thiner again. D. E. H.

Chicago, Ill.

ANSWER.

Nothing, that I know of. Three years settles that, so far as any doctoring is concerned.

BLACK LEG.

I had an outbreak of black leg and lost several head. I would like to know what treatment you consider the most successful in that disease. Is vaccination a preventive?

Towanda, Kansas. I. G.

ANSWER.

I never recommend any form of treatment to a layman for anthrax. It would be wrong to do so. Anthrax is the master of all science, so far as my experience goes—in fifty years. None but the skilled professional man has anything to do with so-called black leg. The environments and every thing else are to be closely examined, as well as the stock. The cause must be removed, before all else.

BONE SPAVIN.

I have a horse that has a bone spavin. It makes her lame when driven on road. How long will I have to let her stand?

Rearville, N. J. L. S. Z.

ANSWER.

Let the horse rest. No living man can take off a spavin, excepting he takes the leg off also, the otherwise boasts of innumerable quacks to the contrary. The best thing to do is to rest the animal, and when *all* the inflammation is gone have some practical, experienced man fire the spavin.

FOOT ROT.

I have a 10-year-old mare, that for two successive springs has been troubled with, what seems to be. thrush, or foot rot of some kind, in her hind feet. Being allowed the freedom of a box stall, which for two weeks was not cleaned properly, she contracted the disease, one year ago, and it proved to be very obstinate. Her feet were washed thoroughly, daily, with warm water, containing carbolic acid, for several weeks, and twice a week a knife was used, and each time some new spot was found to be affected, in the frog or under the shell of the hoof itself, or under the shoe, and was scraped and cleansed with a mild solution of white vitriol. A little carelessness has brought it on again. Similar treatment is being given the feet now as last year, but again it is very obstinate. The diseased portions of the hoof and frog have a very offensive odor, and the hoof crumbles when affected, while in the frog and heel the spots contain a dark, watery substance, very offensive. The same trouble like rheumatism, seems to affect her legs and back. G. H. W.

Earlville, N. Y.

ANSWER.

Stop the carelessness, and keep it stopped. Inject compound tincture of myrrh and aloes daily, until not needed. Why ask what ails the mare when you have told me? Ask yourself, would you like to work when lame and in pain? Let her rest until at least, better. After getting well, clean out the feet with salt and water quite often. Keep cleaned out every morning.

CURE FOR MILK FEVER.

Please give me a preventive and a cure of milk fever. We have a small herd of 20 cows and 4 died last year. S. H. W.

Pylesville, Md.

ANSWER.

I don't know of a cure for milk fever. No one else does, though, maybe 6 per cent may get over it by close application of knowledge acquired. The cure is in the prevention, keep bowels loose by physic constantly for 6 weeks before calving. Keep in poorish condition, always. If a heavy milker, milk 3 to 5 times a day, but, never milk clean, but just a little at a time to keep down distention.

LAME JOINT.

I had a cow that slipped and has caused a lump on her joint about like a hen's egg. She is lame on it; I lanced it and nothing but blood came. I have used hot water and hand rubbing, but of no use. J. T.

Iroquois, Ont.

ANSWER.

Opening by lancing ruins hundreds of cows and horses. You don't say exactly how or where situated. Keep wet with strong oak bark solution; to each quart add half a pint of acetic acid—not more. If upon the joint, you will be likely to always have a chronically lame cow.

INJURY TO COLT.

I have a colt that has a running sore on his pastern joint, that is, just above the joint, it is all swollen. I can get it to heal, but it soon breaks again, and it runs a kind of yellow pus. I notice now that it seems to be affecting its body; it has small risings coming on the body about in places, but the worst trouble is just above the hoof. J. K.

Enterprise, Miss.

ANSWER.

You have a clear case of quittor. These are always bad to manage; your best course is to have a true veterinary surgeon examine the foot and then cut off all superfluous hoof to the bottom, and then cleanse and then try to heal. I can do you no further good, as the treatment of quittor is complex and quite difficult to doctor, always. If snake bite, the treatment will be the same, as the hoof is so much diseased.

CALF SCOURS.

Lately several calves, as soon as born, are taken with a diarrhœa, a white, watery and frothy discharge, lose appetite, eyes sink into the head, they become weak and finally the excrement has a fetid odor, etc., and death results.

To the last one I gave "bicarb soda, barberry and cayenne pepper" and in about three days thought the calf was O. K., but it suddenly sickened, bloated up considerable and died. E. G. S.

Athens, Ohio.

ANSWER.

Diarrhœa is oftener the result of disease than in itself a disease. The reason so many forms of doctoring fail, is, just because all cases are treated as for one cause. Usually a clean change of diet is the first thing to do. Give 4 ounces of castor oil, 2 drams of laudanum, 1 scruple of nux vomica, once a day for a while. Follow this up with slipery elm and carraway seed tea, strong, 1 pint twice a day. Remove all the discharges at once, separate the animals.

LEUCORRHŒA.

One of my cows has been attacked with leucorrhœa, and injected to it, by the vulva, the following, taken from the DAIRYMAN: Half a dram of chloride of zinc in one pint of water, with four to six ounces glycerine. I have done this for from 25 to 30 days, and follow on. Gave internally, as stated: ½ drachm nux vomica, ½ ounce gentian, ½ ounce ginger, 2 ounces old whiskey 4 ounces tepid water, every other day, for 4 doses. She was served on the 6th ot November, '98, and has not taken nor wanted bull since. Do you think she will get all right of the disease, and is she in calf? She has been improving in flesh, and is taking her feed better than before the treatment. J. M.

Guatemala.

ANSWER.

Time only can tell if in calf or not. I do think she will get all right. In fact, she is now all right, I think. If she repeats the whites, let me know, and I will advise you further.

SWELLING ON SIDE OF HEAD.

I have a cow whose head commenced to swell on one side just over the eye and the eye is swollen and bulges out now. It runs somewhat and seems to pain her a good deal. The other eye also seems affected; she eats but little and is growing poor.

Dartford, N Y. C. H. W.

ANSWER.

I never recommend any treatment for so important an organ as the eye when in the condition you describe, but leave the case to a truly professional man. One thing I can recommend, full dose of physic. This will relieve the painful pressure you name. The physic is to be repeated as may seem to be needed. Cold applications constantly applied will do much good. Keep in a darkened room until not needed.

Pasteurizing at High Temperature.

In my leaflet on "The Pasteurization of Milk and Cream," published by the Department of Agriculture last winter, the following occurs: "No experiments, so far as I am aware, have yet been instituted to decide the exact limit of heat that may be employed in pasteurizing milk or cream for buttermaking (without imparting a cooked taste to the butter), but, whereas a few years ago 158° to 165° F. were the temperatures generally employed in the Danish factories, I notice of late a tendency to employ considerably higher degrees of heat, reaching even to 185° F.

The uncertainty of our knowledge on this point at the time of writing, and the fear of that cooked taste, led me to err on the side of caution by recommending a lower temperature for the pasteurization of cream or whole milk than is required for the destruction of tubercle bacilli. Consequently where tuberculosis is feared, and it is important that the factory by-products be rendered completely safe—as in most places, unfortuately, is not the case—this cautiousness on my part had the effect of somewhat magnifying the practical difficulties of inaugurating an efficient system of pasteurization, such as would give the buttermaker perfect cream and the supplier safe skim milk. By way of a postscript to my pamphlet, I would, therefore, like to acquaint New Zealand dairymen, through your valued columns, of the result of a series of experients recently carried out here in Denmark on this very point.

As I remarked in the pamphlet already mentioned, the germs of tuberculosis can only be destroyed with absolute certainty by exposure to a temperature of 185° F., although a slightly lower heat, if sustained for a considerable time, will effect the same result. To maintain milk or cream in large quantities at a high temperature for even 20 minutes or half an hour, is in dairy practice by no means easy, and we are compelled to use the higher temperature, applied only for a few seconds as the milk passes through a continuously fed machine. Now, unless we may submit the whole milk to 185° F. without imparting a cooked flavor to the resulting butter, it becomes necessary (1) either to pasteurize the skim milk by itself at that temperature and the cream by itself at a somewhat lower temperature—in which case the closer skimming to be gained by pasteurizing the whole milk must be sacrificed—or (2) to pasteurize the whole milk by itself at such lower temperature as will not impart a cooked taste to the butter, subsequently treating the skim milk to a second and more drastic pasteurization in order to insure death to the tuberculosis germs.'

The difficulties suggested by this question evidently occurred to the Danes also, for during the past year a large number of experiments have been carried out to determine, once and for all, whether milk or cream could be carried to 185° without injury to the flavor of the butter. For those who wish to secure the closest possible skimming by pasteurizing the whole cream and who at the same time expect a butter free from the slightest cooked flavor and skim-milk innocent of a single live tuberculosis germ, the results will be welcome as greatly simplifying the modus operandi. For the answer to the question is a most decided yes—provided, however, that the cream be immediately and quickly cooled to at least 55°.

In the prompt and thorough cooling of the cream lies the crux of the whole question. Even 195° was repeatedly employed without any permanent cooked flavor being at all noticeable, so long as the cooling was efficient. Please note the word "permanent" for although the butter may have had a slight peculiar flavor when first made, this invariably disappeared in the course of one or two days. Comparisons between butter made from milk or cream pasteurized at 185° to 190° and from portions of the same cream heated only to 170° showed that not only was the former as good, but, in most cases, was better than the later. But remember the cooling is as important a part in scientific pasteurization as the heating itself.

The details of the experiments, interesting though they are to students of dairying as affording a beautiful example of how dairy research ought to be conducted, are too voluminous to record here. Fifty-two complete experiments were made, covering all seasons of the year and carried out in four different localities, while every possible precaution was observed to eliminate outside influences which might affect the results. Trustworthy and unbiassed judging was secured by having three separate judges, and examining every sample a second time at an interval of fourteen days. In short, the verdict may be accepted as dairy gospel, tried by every test that man's ingenuity could devise. Chemical analyses were also made of the buttermilk and of the moisture in the butter. The percentages of fat left in the buttermilk and of water in the butter were not in any way affected by the higher temperature.

While on the subject, it may intrest you to know that out of the 713 factories competing last year in the Danish "State Butter Shows," all except five pasteurized the whole of their output—four of these five had the unenviable distinction of occupying the four bottom places in the official list, while the fifth was not much better—and all but eleven used "commercial starters." For the last two years, no case of "fishiness"—New Zealand's bug-bear—has been scheduled by the judges, and this fault may therefore be considered a thing of the past in Danish dairying—rooted out by cleanliness, pasteurization and the use of a good, clean starter. With regard to moisture, 2,110 packages analyzed showed an average of 13.9%, considerably more, I fancy, than an equally comprehensive examination of New Zealand butters would reveal. The lowest percentage of moisture recorded was 10½%, but only 60 of the 2,110 packages held less than 12%. C. W. SORENSEN in *New Zealand Dairyman.*

How He Succeeds In Dairying.

A McHenry Co. Ill., farmer writes the following letter to the Practical Farmer giving his ideas and practices in the management of cows:

"We dairymen here in Northern Illinois know that the only sure road to success in the dairy is by way of kindness.

Having lived on a dairy farm all my life, my mind goes back to the time when as a school boy, I used to have the calves to feed, and drive the cows to and from the pasture; I therefore speak from experience. It was then I learned through kindness we can make nearly all domestic animals love us.

The cow may be termed a laboratory, where milk is produced from the food she eats and the water she drinks, and she can not be expected to turn out a good article unless supplied with wholesome food and good water. I insist on our cows having kind and gentle treatment. I never allow them to be dogged or run while going to and from the pasture. We never misuse our boots or milking stool in attempting to reform an unruly or refractory cow.

Nine times out of ten the remedy will make matters worse. If she cannot be overcome by kindness she is worth more to the butcher than for a dairy cow. I give my cows daily out-of-door exercise in winter when weather will permit, but never expose them to severe storms. I salt my cows often; that is the way they like it. If their teats are sore or cut I apply a good healing salve and keep my finger nails trimmed closely. For all these little acts of kindness she repays me grandly.

I take special care in preparing milk for the factory. I get a can of hot water at the factory, and with a liberal quantity of Gold Dust washing powder give the cans, pails and strainer a thorough cleansing each morning, so they will be well aired before using. Milk must be well cooled and scrupulously clean for best results. Do not depend too much on the strainer. If dirt is allowed to get into the milk it cannot be all taken out.

I have drained my slough pasture by ditching. I do not allow them to go to pasture in the spring until the grass is well started, usually about the middle of May. Therefore, there is no mud for them to wallow in. If the udder gets fouled from any cause it must be washed before milking.

I keep the stables well cleaned and liberally supplied with bedding. I use the refuse of shredded or cut corn-fodder for this purpose, as it will rapidly absorb the liquid manure so the barn will be comparatively dry and free from foul odor, which is sure to taint the milk. We air our stables thoroughly each day and keep the mangers clean for the cows eat with their noses in the dish and their breath fouls the food if too much food is given them at once. By observing these precautions our cows keep clean, and with proper care in milking we have clean milk. As a successful physician requires his patients to take their medicine promptly on time, so we, to be successful dairymen, must be good farmers, prompt, systematic business men, and above many things, on time.

We milk, feed and water our cows regularly. I set the alarm clock to ring us up at the same time each morning. The milkers have the same cows to milk all through the season. I never allow changing unless in case of emergency. The milking is done as rapidly as possible after commencing. I water twice per day in yard, from 8:30 to 9:30 a. m., and from 4:30 to 5:30 p. m. I clean the stables twice per day while the cows are in the yard, exercising or drinking. I feed liberally of shredded corn-fodder twice per day, and hay once; also corn meal, ground oats and bran, mixed, from two to six quarts, according to condition of cow, twice per day. I also feed some oil meal or stock food in winter.

Reducing the cost of production is a subject that is puzzling the majority of dairymen. In these times of low prices and close competition nearly all profits depend upon reduction of cost. Our cows are the machines for converting the grains, corn fodder and hay into a marketable commodity, namely: milk. The first requisite for this purpose is a good machine. A poor cow is an unprofitable investment. I plant from eight to ten acres of thick-drilled corn, part being Evergreen sweet corn, which generally proves a good investment.

An immense amount can be raised to the acre, and it is better than hay for winter feeding, after running through the fodder cutter. Also in case the pasture should fail from protracted drouth, it can be fed green. In this way I keep up the milk flow cheaply, which would be quite expensive otherwise I also plant about thirty acres of field corn in check rows. We cut and shock it all, putting 100 hills in a shock. We husk it with a corn husker and shredder, the fore part of November, running the shredded fodder into the loft of cow barn right over the cows, where it will be handy to feed, and in ricks at side of barn. I consider this green, bright, shredded fodder worth as much as the same amount of hay, or more, for milk production. I feed quite a large amount of bran, and as I cannot grow a substitute for it on my farm, I must buy it. I therefore gave my orders for a car load of it. It cost $9 per ton delivered last summer. Now, if I had bought this bran along as I wanted to use it, of our local feed dealers, it would have cost from $12 to $15 per ton, and perhaps I would have had to haul it over bad roads. Now, friends, these are the lines on which I have been trying to reduce the cost of production in keeping my dairy. But in figuring up our profit or loss, I always take into account the increased productive value of our farm from manure. Now there is an endless variety of details which can not be written, connected with our dairy farm; and on their proper execution success or failure very much depends. These must call into action the best judgment of our up-to-date dairymen. I read the best dairy publications. Here is where I come in contact with the wisest and most profitable experiences.

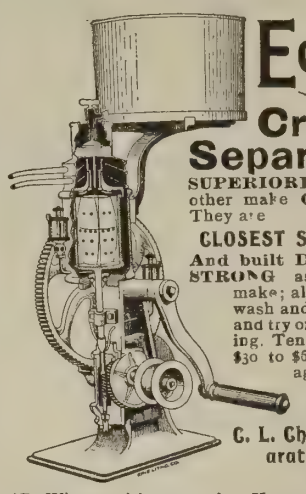
Washing Milk Utensils.

ED. HOARD'S DAIRYMAN:—The time of year is fast approaching, when if proper care is not exercised in keeping all milk utensils perfectly sweet and clean much milk will be lost by souring and much time wasted in washing cans, pails, etc., in which the milk has soured or dried on the sides. It is frequently the practice at creameries to leave the weigh can, milk and cream vats, and tanks unwashed for several hours after using, not realizing that the delay causes extra labor.

At the Kansas Agricultural College dairy a few days ago a number of sample bottles were necessarily left unwashed until the next day. It took just three times as long to wash them as it did on other days when they were washed as soon as the milk was thrown out.

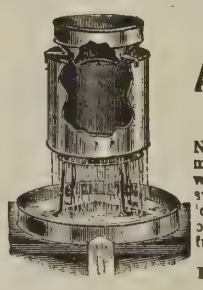
In washing milk utensils, they should first be rinsed out with cold or tepid water, then wash in water as hot as the hand can stand, and finally scalded thoroughly, and then if possible set out in the sun. If more care is used in cleaning the pails, cans, etc., there will not be so much sour milk sent back from the creamery; the patron will feel happier and so will the creameryman.

Kansas Exp. Sta. J. A. CONOVER.



Farm Wagon for only $19.95.

In order to introduce their Low Metal Wheels with Wide Tires, the Empire Manufacturing Company, Quincy, Ill., have placed upon the market a Farmer's Handy Wagon, sold at the low price of $19 95. The wagon is only 25 inches high, fitted with 24 and 30 inch wheels with 4 inch tire.



This wagon is made of best material throughout, and really costs but a trifle more than a set of new wheels and fully guaranteed for one year. Catalogue giving a full description will be mailed upon application by the Empire Manufacturing Co., Quincy, Ill., who also will furnish metal wheels at low prices made any size and width of tire to fit any axle.

SWAMP-ROOT Is not recommended for everything; but if you have kidney, liver or bladder trouble it will be found just the remedy you need. At druggists in fifty cent and dollar sizes. You may have a sample bottle of this wonderful new discovery by mail free, also pamphlet telling all about it and its great cures.

A Perfect Milk Wagon

On a Perfect . . . Short Turning Gear

We make the only drop center wagon that has a self-balancing, short turning gear. All parts are wrought iron forgings. It is so plain and simple that it can't get out of order and if any part should break, any country blacksmith can easily repair it. All other wagons of this kind have complicated gears, and mostly made of cast iron.

Write us for our Catalogue, which fully illustrates and describes this wagon and 10 other styles.

THE NEW BOOK
Feeds and Feeding

By Prof. W. A. HENRY.
Wisconsin Experiment Station.

This book should be in the hands of every stock feeder in the country. Every reader of HOARD'S DAIRYMAN ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

or

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehensive from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be referred to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price $2.

Lest you forget,

we say it yet:

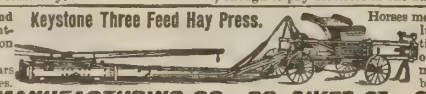
SMALLEY CUTTERS

are much the best for

SILO WORK.

SMALLEY MFG. CO., Sole Makers, Manitowoc, Wis.

KEYSTONE QUICK HAYING MACHINES.



Keystone Side-Delivery Rake *means "Quick Haying, Quality Prime."* Turns the hay completely and leaves it in a light, loose windrow ready for loader. Its use means air cured, not sun bleached hay. Better than a Sulky Rake and saves use of tedder. Rakes wide, fast and clean. Takes up no trash, that means clean hay.

Keystone Hay Loader. Loads the hay from the windrow or cock, or direct from the ground if the hay is heavy. Takes the hay up clean but takes up no manure, rubbish, &c. It makes haying quick and easy. In showery weather it often saves enough to pay for itself in one day. Loads a wagon in 5 minutes.

Made entirely of steel and iron. Horse power only. Mounted on steel wheels, and stands on the wheels when operating. Write for our special circulars fully describing these machines.

Keystone Three Feed Hay Press. Horses move in a full circle. Each revolution moves the plunger three times—one more feed than any other press made. Requires no more men but increases capacity beyond comparison.

KEYSTONE MANUFACTURING CO., 39 RIVER ST., STERLING, ILL.

Make Your Own Guarantee.

We have so much faith in the Sharples TUBULAR Separator, and it has so frequently and so persistently demonstrated its ability, superiority and economy that we are willing that every purchaser should practically make his own guarantee. Therefore, to make yourself entirely secure, you may write the following in your purchase contract:

Please ship to me a Sharples TUBULAR Separator. I will immediately put it into my factory and give it a fair and careful trial. If I like it in every respect, and it does all claimed for it, I will keep and pay for it. If it fails to suit me for any reason I will notify you to that effect, and on receipt of instructions from you, will re-ship to your order as you may direct.

Could anything be more fair or liberal than this proposition? Do you suppose for one moment that we would make such a proposition if we did not know just what we are talking about and just what our machine will do?

Have you ever heard of another separator concern that was willing to make such a broad and liberal proposition? It is because . . .

THE SHARPLES TUBULAR SEPARATOR

IS BUILT UPON HONOR and SOLD UPON ITS MERITS.

These qualities make it a winner even against the most unfair and unreasonable competition.

It is a safe machine.
It has large actual and reserve capacity.
It is a clean skimmer—from .05 to nothing.
It is economical in power, oil and repairs.
It makes the smoothest, most churnable cream.
It increases the yield of butter and makes better butter.
It is a reputation builder, and
It is a money maker.

Cooling Cream With Ice.—Elevating Skim Milk.

ED. HOARD'S DAIRYMAN:—Would like to inquire if there is anything to justify the practice of placing broken ice in cream at any time, or in any of its stages from time of separation to being churned, to cool it to desired temperature. What are the deleterious effects, if any? Has icing cream just before churning bad effects?

When skim milk is taken from separator by curved tube, through the small hole in which it passes and is elevated ten or twelve feet, is not the elevation accomplished to detriment or at expense of power to speed the bowl?

F. E. M.

Schuyler, Neb.

The use of broken ice for cooling cream, is a very common method. It is a very quick and easy way of doing the work and in places where the supply of cold water is not good, the use of ice in hot weather is perhaps the only way in which the proper temperature for churning and the production of butter with a good grain, can be obtained. If all ice were clean, there would be no objection to its use in the cream, but we have seen lumps of ice put into the cream, that when melted, showed a ring of black on the surface of the cream.

Common sense teaches that such dirt is not good for either cream or butter, but so long as water and cream are warm and ice cold and handy, it is probable that ice will be used for cooling cream, regardless of the amount of dirt introduced.

No, but you should get your cream to the churning temperature sooner than "just before churning," if you want exhaustive work.

It takes power to elevate skim milk, whether it is done by the separator bowl or a pump.

Of course there must be enough extra power supplied to the bowl to do the work of elevation, and the greater the elevation of the skim milk, the more power will be necessary.

New York Farm and Dairy Notes.

The Work in the Hay Field.

ED. HOARD'S DAIRYMAN—In this locality we like to begin haying the last week in June. I think all farmers do not appreciate the difference between the early cut and the late cut hay. I think that one third and perhaps one half its value is lost, when the grass is left standing until the seed has formed. If I could begin haying when the first blossoms appear, and cut it all in one week, I think I would get the very best hay.

With a large haying, taking into consideration the uncertainties of the weather, one can hardly expect to finish haying in one, or in two weeks, so I prefer to commence a little before the blossoming time when possible, for I would rather cut the grass when it is too green or immature, than when it is too ripe. It is the very best economy to feed early cut hay—hay that contains in the stalk, all the nutritive elements, a part of which, at a later stage of growth, may pass into the seed. With the early cut hay the stock will require less grain to make the same growth, or produce the same quantity of milk.

It is only the older men that realize how the work of haying has been facilitated by labor saving implements. Forty years ago about the only haying tools were the scythe, hand rake and pitch fork. Now the latest improved wide cut mowers cut the grass at the rate of eight or ten acres per day, the hay tedder soon fits the hay for raking, and the new side delivery horse rake places it in heaps ready for loading on the wagon, or on level, smooth ground, one may use the hay loader which takes the hay from the ground as left by the mower, if the hay is heavy, or from the windrow, and loads it on the wagon. The hay can be unloaded with the horse-pitchfork, thus avoiding all the hard work of the old way of haying.

In these times all farmers use more or less of the improved haying implements, according to the condition of their ground and their available capital. With the implements we have for storing the hay crop so rapidly, it hardly pays to mow grass, unless we have reason to expect a few days of good hay weather. The weather reports which are now sent to most of the post offices will be of use to many farmers in planning their work, and farmers living near the post offices should watch these reports closely in haying time. The clover needs special treatment in curing, to make good hay. When rightly managed, it is the best hay we have, and its special value is for feeding with ensilage, for it is rich in protein that helps to balance the excess of carbohydrates in the ensilage.

The growth of clover on our farm has been very large, and our plan has been to start the mower when we thought we could expect two or three days of sunshine, after the dew was off in the morning, and mow until noon. In the afternoon, the clover cut in the morning was dried all we could by tedding it, and just before night, was raked and put in small heaps. If the weather continued good, the hay was left in the heaps for two or three days before drawing to the barn. A few hours before drawing them the heaps were turned over and opened to give the hay better aeration and exposure to the sun before storing it. This method makes better hay than the one of leaving it as it is left by the mower to cure.

WHAT TO DO WITH THE SKIM MILK.

On many farms where butter is made or the milk is taken to the butter factory, and the skim milk returned to the farm, it is a question with many as to the most profitable use to make of it. Shall we feed it to hogs, calves or poultry? The skim milk is certainly the most valuable by-product of the dairy, and we wish to utilize it in a way to realize the most from it. The best disposal of the skim milk will depend on one's circumstances. Whether he shall feed hogs, calves or poultry, depends so much on the home market for them, that it is largely a local question.

As I am situated, I can get the most from the skim milk, to feed it to poultry, but of course I advise raising the calves that are needed to replace the cows in the dairy, that fail to be profitable. Farmers having plenty of skim milk for chicks, and a large run for them where they can pick up worms, insects, seeds, etc., can grow chickens at a small expense. For my chickens I can get ten cents per pound, and for pork or veal I could seldom get over five cents, and I think it costs no more to produce the pound of chicken.

It is more especially the farmer who keeps a small dairy who can make the poultry business in connection with it, profitable. The hens usually pay well that are fed skim milk, and it is very valuable for chickens because it is rich in bone and muscle making material. The cream that is removed is mostly fat, which can be supplied to make a balanced ration by feeding more corn in connection with the skim milk. When feeding skim milk to chickens, I feed only the curd, for there is little value in the whey. If I were a young man with only capital to buy a small farm, I would think that in the right location the best opening for me would be to buy a small dairy farm, on which I could keep as many cows as I could care for alone, and keep sufficient poultry to consume most of the skim milk. This is a question that should be well considered; how the most can be realized from this very valuable by-product of the dairy.

W. J.

Delaware Co., N. Y.

A CLEAR DEFINITION.

Judge Stockbridge, of Baltimore, seems to have a very clear understanding of this oleomargarine question and the law which is aimed at its sale as counterfeit butter. In a charge to the jury in a recent case in the city, he said:

"The offense consists not in the manufacture and sale of the article, but in the manufacture, sale, or offering for sale of it 'in imitation or semblance' of natural butter; that is, the section is aimed at the prevention of the perpetration of a possible fraud upon the public."

The above opinion is the gist of the sentiment of the dairymen of the United States, and is the animus and inspiration of all their effort to secure laws, both state and national, that shall diminish the sale of a fraud and deception.

Don't Let Cows Get Tired - 382

THE average cow with a beef tendency is going to put her surplus food on her ribs and back, rather than in the milk pail, and no method of feed or handling is going to prevent it. The small amount of fat which overflows into the milk pail, is accidental rather than intentional; it being easier to make tallow than butter, she follows the easiest path.

The dairyman has the pleasure of feeding such an animal for from four to ten years and gets as his return a small amount of five cent beef and three cent fat—losing at both ends.

THE cow that was sheltered from the north winds of last January by a rail fence and fed a ration of frozen corn stover and straw, is now fighting flies and walking many miles a day, picking up her living from an old, worn out, dried up pasture. Her owner knows that "dairying don't pay," in which conclusion he is perfectly correct. It never will pay under the conditions of feed and care under which he compels his cows to live.

The best cow in the world cannot make profitable returns without the best of care and feed. What a poor cow will do on poor feed and worse care, needs no prophet to foretell.

IN Mr. Wheaton's Canadian Dairy Notes, on page 356, of last week's issue of the DAIRYMAN, he speaks of a United States firm that has got itself justly into trouble by shipping 150 packages of "ladle-packed" butter to England, that contained 15 per cent of foreign substances. On this point Mr. Wheaton observes:

"It is hard to conceive that an ordinary creamery, even on your side of the line, would be guilty of palming off such "spurious" goods upon a reliable shipper, as a pure quality of butter, and yet it has been done, and it is the doing of this kind of thing that is ruining the export butter trade of the United States."

As a rule "ladle" butter is not handled at a creamery. This business is usually carried on in the cities, and the country creamery has nothing to do with it. But Mr. Wheaton's remarks about this constant swindling of consumers by fraudulent mixing and adulteration of food, are everlastingly true.

What with "embalmed beef," "process butter" mixed with poisonous preservatives, oleomargarine colored and sold as butter, "glucose sugar," and hundreds of other adulterations and food swindles, it is a wonder we have any export trade whatever.

Something must be done at once by the general government, to save the commerce of the United States as well as the health of its people, from destruction by this great army of swindlers, who prey like wolves upon every honest industry about them.

FEEDS AND FEEDING.

In the business of dairying, from fifty to seventy-five per cent of the total expense of maintaining the dairy herd is required directly or indirectly for food. If greater profits are to be secured, they must be largely reached by cheapening the cost of food.

In regard to this matter of feeding dairy animals, Prof. I. P. Roberts said, at a dairy meeting in New York, that to maintain a cow of 1,000 pounds live weight, on clover hay alone, would require thirty-five pounds a day. This would furnish of digestible material 2.38 pounds of protein and 13.86 pounds of carbohydrates (including fat multiplied by 2.25), very nearly a standard ration. Fed through the stabling period of two hundred days, the cow would consume three and one-half tons of hay, the cost of which would be $24.50, an amount nearly equaling the value of the products of many single cows. Then, too, the cow would eat thirty-five pounds of hay a day with difficulty. In addition, the cow would require pasture for one hundred sixty-five days, which would add about $6 more to her food cost. At a yearly cost of $30.50, the ordinary cow would give little profit.

Under the foregoing conditions, it would require about five acres to keep one cow a year. With mixed hay or timothy, the results would be even less satisfactory.

One subscriber of the DAIRYMAN writes us: "I wish you would stop figuring up so much on us fellows, who don't feed with sense or who don't have cows that are worth their feed. Your confounded figures make us uncomfortable, and we are bound to be comfortable, if we don't make a cent."

DILUTION SEPARATORS.

Inquiries are constantly being received regarding the dilution or hydraulic separators. It is evident that large numbers of them are being sold and that claims are being made as to their efficacy in separation, which are unsupported by facts.

The dilution separator is a tin can with a faucet at the bottom, and more or less complicated in construction by tubes for the addition of water or as a means of introducing air, or other so-called improvements. The tubes add nothing to the efficiency of the machine, and only are a pretext for charging $10.00 to $15.00 for a tin can, which without them would be worth one to two dollars.

Everything claimed for the hydraulic separator, can be equally well done in a shot gun can, and if water below 40° F. can be obtained, or ice to bring the temperature down to 40° F., the thoroughness of separation will be far superior to any hydraulic separator.

The only case where there is any advantage in using the method, is in milk from cows far advanced in lactation, and then the efficiency of the process is about equal to deep setting in ice. They are no more efficient than the old-fashioned shallow pan setting, with the disadvantage of greatly increasing the volume of skim milk to be handled, and in case hot water is used, as is sometimes advised, there is the added inconvenience of the rapid souring of the skim milk.

If any dairyman wishes to try the method there is no patent to prevent his using the process to his heart's content. Numerous patents have been granted on the various forms of cans used, but these are of no particular value, except to their owners, and certainly are not worth to any dairyman the $10 00 or $15.00, which are asked for the so-called "hydraulic separators."

WHY HE BREEDS JERSEYS.

One man likes Holsteins, another Guernseys, another Jerseys, and the fourth Ayrshires. Quite generally, it is a matter of taste, or may be prejudice. Yet it is wise for a man to follow his taste in selecting a breed, for there is a subtle law involved here, whereby an animal always does better with an owner that likes her.

But it is always interesting to read or hear a reasoning man's reasons for any course of conduct. Mr. C. I. Kingsbury, of Oswego, N. Y., writes the *Jersey Bulletin*, giving the following statement, why he prefers Jerseys to any other breed:

When I began, about ten years ago, to manage the dairy, which during my boyhood I had helped to raise, and which in turn had helped raise me, I thought we had some pretty good cattle, and supposed from my reading in farm papers, and what I could learn at farm institutes, that all I needed to do was to have a winter dairy to make money. Accordingly, I had five cows fresh in the fall, and with five farrow I commenced winter operations. The cows gave 100 quarts per day, the butter was sold in prints for 25 cents per pound, and everything was all right, except the amount of butter; from those ten cows and 100 quarts of milk I got less than six pounds of butter per day, usually a fraction over five. This $1 25 to $1 40 per day would leave but a few cents a day after paying for the bran and meal bought, to say nothing of hay and care of cattle, labor of butter making, etc.

About this time, a milkman wanted some milk at three cents per quart, and that three dollars per day looked very large. I learned, at this time, that a cow may be valuable for one purpose, and worthless for another, and that a liberal milker may be a poor butter maker. This does not sound as new as it did twelve years ago, but there are people who have not learned it yet.

At a venture, I bought two Jersey heifers; it took the price of eight heifers, of about the same age, sold for beef, to buy them. I could only sell milk for a few weeks—I must make butter most of the time; those eight heifers would, probably, not make any more butter than their dams. The more I owned of them, the poorer I would become; invested in two Jerseys, I should have six less mouths to feed at least. The others are all right to sell for beef, but I wanted something that would not bankrupt me during its life.

The first heifer, Edith of Suwasset 60486, freshened at eighteen months; gave eighteen pounds of milk a day, which made eighteen ounces of butter; the next year twenty-eight pounds milk per day, and twenty-eight ounces of butter; the next year, from thirty to thirty-five pounds milk per day, of the same richness.

The other heifer, May Regina 65897, her half sister, was fully as desirable a cow. I sold her as a 3-year-old, and her owner reported, the next year, a test of sixteen pounds in seven days.

There is much difference between feeding one cow for two pounds of butter per day, and feeding three cows for the same amount—that difference is the reason I have continued to breed Jerseys.

Farm Experiments.

ED. HOARD'S DAIRYMAN:—It is no disparagement to the work of our different experiment stations, to say that there is a kind of investigation which they can never perform. The principles on which successful farm practice must depend, may be properly and effectively studied by these institutions, but in the practical application of the results thus secured, there remains much which can only be successfully accomplished on the very farm to which the principles are to be applied. The infinite variety of soil and climatic conditions, to which all crops are necessarily subjected; the wide differences which even individual farms offer, preclude the possibility of securing in any one locality, the detail of data which shall control successful practice in all other localities and farms, of the same political division. Upland and lowland, sand and clay, hard wood lands and pine lands, dry lands and wet lands, all offer local peculiarities demanding variations of practical treatment, which cannot be studied under opposite conditions, and which render the results obtained under one condition, wholly inapplicable to another.

It seems, therefore, obvious that our official stations should devote a larger part of their efforts to the elucidation of principles, and to the developement of schemes and systems for private investigation, and less time to the routine of plot trials, and variety tests, which can have only local application, and many of which are better and more effectively conducted by parties whose commercial interests are involved. To illustrate:

The opinion or judgment of a reliable nurseryman or seedsman, always obtained as a result of personal experience and trial, is usually a safer guide to the selection of trees, plants, seeds and fruits adapted to the locality in which he is located, does business, and has financial interest, than any advice furnished on the same points by the experiment station located, possibly, many miles away, and with soils and climatic conditions quite different from those involved.

It is not possible to suggest a plan of individual experimentation which shall be universally applicable, but a few suggestions as to the conditions to be met, and the methods best calculated to secure trustworthy and useful results, seem feasible.

The location should be, as nearly as possible, the average soil of the farm, as convenient of access as possible, and with an even aspect and drainage. The area devoted to the purpose must be controlled by the extent of the work contemplated. The site should be carefully divided and measured into plots, between which vacant spaces of not less than three feet in width must be left to prevent, as much as possible, the effects of the treatment of one plot from effecting the results of its adjoining neighbors. The size of these plots will chiefly control not only the area required, but also the reliability of results.

The common mistake in opinion and practice, is that of too large plots. Really, the smaller the plots up to the minimum of practical working with farm methods and implements, the better; one-tenth acre may be given as a maximum area, and one-hundredth acre is probably a better, and possibly the minimum feasible size of plot. The reason for this fact is not far to seek. Results must all be based on averages, and it must be obvious that 100 trials on 100 plots occupying an acre of ground must give greater probability of average correctness of conclusion than though the results were secured from a single trial occupying the entire acre.

The nature of the experiments to be undertaken will commonly fall within three different groups. Variety trials, for testing promising novelties. Method tests, for the study of methods of cultivation and treatment; and last, feeding experiments, for testing the value of different forms, sources or mixtures of plant foods.

The first is doubtless the least important, and the last class of experiments is that offering greatest prospect of definite and practical results to the experimenter. On this latter point a few suggestions may be useful. Under average conditions it is folly to devote time and funds to the effort of learning which of the three essentials, phosphoric acid, nitrogen or potash, when used alone, is most productive on any given soil. Economy dictates the use of all three; all average soils require all of them, and the

problem is in what proportions are the best crops produced?

Probably the most complete line of fertilizer experiments undertaken in this country, is that started in 1895, at the Experimental Farm of the North Carolina Horticultural Society, located at Southern Pines in that state. The work is under the immediate supervision of the State Agricultural Experiment Station and the object is to determine the best method of manuring and cultivating fruits and vegetables. The experiment farms are practically in the center of a tract of many thousands of acres substantially the same, so far as soil and climate are concerned. The system of fertilization adopted includes different combinations of phosphoric acid, potash and nitrogen as well as a study of the action of these food ingredients in different forms. The results from this farm will, no doubt, be of great value to the agriculturists of this country. H. E. STOCKBRIDGE.

Cost of Starting a Dairy of Fifty Cows.

I have received, from a correspondent, several inquiries in connection with a proposed dairy of fifty cows, that he thinks of establishing. I will be very glad to assist him, if I can do so, to get his dairy started. I believe dairying the most promising line of farming for this section.

I do not oppose the editor's well-known enthusiasm for hay farming, nor do I advise everybody to go into dairying. Cotton can be grown at a profit, even at present prices, under certain favorable conditions. I do not propose, in this article, to discuss the relative merits of hay, cotton and dairying. I only mention the three systems to encourage Mr. N., and perhaps others who are thinking of going into this comparatively untried branch of Southern farming. I do not believe it possible to make a failure if dairying is gone about in the proper way.

I will not repeat Mr. N's. inquiries, but my replies will indicate the points he asks information on.

To properly house fifty milch cows will require a room 36×75 feet, but as Mr. N. will, no doubt, want to keep his heifer calves, he will need a much larger stable room. His calves will average, one year with another, about half bulls and half heifers, but allowing for inferior calves and for deaths from various causes, he will not raise more than about fifteen a year, so that he will need room for, say, fifteen calves and fifteen year-old heifers. At two years old they should come in, and either go on the market as milch cows, or what is better, take their place in the dairy and some of the less valuable of the old cows be sold.

To properly house these thirty young things, will require an additional forty feet in length to the barn. He will need about ten box stalls for cows near calving, and for bull and work horses, so that his barn should be 36×150 feet for the accommodation of his animals. If silo is built inside the barn, enough additional space must be provided for it. However, I do not advise loca ing the silo inside; just outside, but immediately in connection with barn, is the best place for this very necessary structure.

This barn may be built in one continuous length or otherwise, as the location or fancy of the owner may suggest. Provide easy approaches to second story for convenience in hauling in hay, grain, etc. It is more economical to haul feed and bedding right into the barn than to undertake to get it there by hand work. When it has been stored it is very little work to get it down to the cows through openings at convenient points.

This building can be erected for $1,000, for a plain box job, on up to a higher figure if desired. This estimate is for a plain serviceable house and is suited to the very best and most economical handling of the cows mentioned.

If I were building a barn of this size and had money to spare, I would spend considerably more. I would frame and weatherboard throughout, and would ceil the lower or stable room with first-class matched ceiling. Would make all gutters and hall floors of cement, and in every way make a first-class job.

I know that most southern writers claim that we do not need winter protection for our cattle, and that they are better for a little rough weather experience, but my observation has been very different. Georgia or Alabama cows need quite as good housing as those several hundred miles further north. While I advise good buildings, when they can be afforded, I would not discourage any one who cannot afford to build them. Dairying can successfully be carried on under comfortable sheds for the cows and cheap storage room for feed but would be more expensive for labor and attention.

I would build for this herd one 300-ton circular silo. If very sure of good pasturage through the summer months, a smaller silo will do. But pastures generally are so unreliable that it will pay to put up ensilage for the entire year and not depend on pasture at all One acre will produce more cow feed if well cultivated than five acres of the same land in pasture. The dairy building should consist of two 16x16 feet rooms above ground, one for storage of shipping boxes, salt, butter. paper, etc , and the other for separator and for washing tinware, etc. There should be a cellar or basement 16x16, eight to ten feet below the surface of the ground, for churning and taking care of cream and butter. This cellar should be lined and floored with gravel and cement; should be drained and provided with pump, etc. This building will cost about $200.

As to comparative cost of feeding ensilage and dry fodder, I will only say that if you do not expect to feed ensilage do not go into dairying. Ensilage is succulent, appetizing and healthful. It is less expensive to handle, requires less storage room, and is practically all saved. Without having made any careful trials, I have no hesitation in saying that one acre of ensilage is worth fully as much as two of the same corn cut and dried. By careful selection you ought to be able in two or three years to have a herd that will give you 300 pounds butter each per annum. Buy a first-class bull and raise all of your best heifers. Keep daily account with your cows and sell every one that falls below 250 lbs. per year. Kill bull calves on sight. I have never kept account of what it cost to raise calves. Only about one in five bought cows are worth keeping, while home-raised heifers from a good dairy bull will nearly all be valuable enough to keep. At least four out of five will be better than their dams, and not having a market for skim milk you can do no better than to raise these heifers. Every mature cow will make from ten to fifteen two-horse loads of manure per year, depending on how long they are kept up and amount of bedding used. This manure is probably worth about $1.00 per load. The chemist no doubt would rate it higher. But I do not think it necessary to count manure values. Be sure to save all, both liquid and solid, and apply to crops and count what you sell only.

The same rule will apply to skim milk and buttermilk. They are rated by various authorities at from 15 to 35 cents per 100 pounds for feeding. But I do not see why we should hunt up a fictitious price for these products, when there is no expectation of selling them. Feed skim milk to calves and heifers and buttermilk to pigs. I much prefer feeding calves than pigs. It will take no more feed to raise a two-year-old heifer than a one-year-old pig. The heifer will be worth from $25 to $50. The pig from $10 to $15. The heifer will be an interesting, lovable animal. The pig a filthy, grunting nuisance.

The amount of land needed to carry this herd will depend on how fertile it is; twenty-five to thirty acres of good land will be enough to grow the ensilage needed; twenty-five tons each of pea hay and oat straw or crab grass hay, will be needed to feed the milch cows. The heifers and calves will need about one-third more. Milch cows will need about four pounds cotton seed meal and four pounds bran each, while giving milk. Calves and heifers will need very much less, probably an average of half-pound of each per head, per day.

The most satisfactory plan that I have yet tried, is to have all barn work done by contract. A family of one man and three children from ten to eighteen years old, is enough for a herd of this size. Make it their duty to do everything in connection with the cow, from feeding on through every conceivable service that comes, up to milking and delivering milk at dairy. I pay my barn man 15 cents per 100 pounds for all the milk he gets. This pays him for all his services, and as his pay depends on the amount of milk he gets, he is interested in having the cows do their best. All the work is done by himself and minor children, and pays them about $35 per month, besides two gallons of skim or buttermilk per day, that is furnished him without charge. Counting everything, he makes about $500 per year. Dairymen will cost from $200 to $300 per year, according to experience and skill.

He will need a No. 3 Baby separator, a small engine and boiler, churn, butter-printer, tinware, etc., for the dairy; ensilage cutter, trucks and milk-cart for barn. These will cost five to six hundred dollars.

It will pay Mr. N. or anyone else that is thinking of going into this business, to visit some established dairy before doing anything. He can pick up more information in a couple of days by being on the ground than I could write in a month. A few dollars spent investigating will be better than a hundred experimenting.—W. L. WILLIAMSON, in *Southern Cultivator*.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

GLOSSARY.

The terms used in this department of HOARD'S DAIRYMAN have the following significance:

RATION.—The total allowance of feed for twenty-four hours.

DIGESTIBLE NUTRIENTS.—That portion of the organic matter which can be digested by the animal and does not pass off through the bowels as excrement.

PROTEIN.—That part of the digestible nutrients which goes to the formation of lean meat, ligaments, hair, horns and the casein (or curd) of milk. It is generally believed, also, that protein may be, and many times is, converted into the fat found in milk. The basis of protein is nitrogen, hence the protein elements are frequently termed the *nitrogenous* parts of the food. They are also called *albuminoids*.

CARBOHYDRATES.—That part of the digestible nutrients which is the primary source of sustaining animal heat and furnishing the power for keeping the animal mechanism in operation. They are composed of the woody fibre of the plant and grain, and the starch, sugar, gums, etc., and in the published tables of chemical analyses are usually subdivided into the terms *crude fibre*, which is the least digestible portion of feeding stuffs and *nitrogen free-extract*, so-called because it does not contain any nitrogen.

ETHER EXTRACT.—That portion of the digestible nutrients which may be dissolved out of the food stuffs by ether. It is frequently called *crude fat*. Whether fat is actually digested and thus passed on into the circulatory system in a changed form or whether it is simply separated from the other elements and always maintains its identity is an unsettled problem. It can be used by the animal for maintaining the body temperature, and for this purpose is from 2.2 to 2.5 times more efficacious than the carbohydrates. It is maintained, by some, that the fat in the milk comes, largely, from the crude fat in the food, but it has been demonstrated that it is not absolutely necessary, for this purpose.

EFFECT OF ACID ON CHEESE.

What is the effect of acid in milk, on cheese?

Albany, Oregon. W. R. S.

It is presumed that the acid meant in this case is the lactic acid, produced by the action of the lactic acid bacteria on milk sugar.

Aside from the action of fermentation on the casin, dilute acids or alkalies have a solvent action on the curd, and cause the particles to adhere when piled. In Cheddar cheese making, the lactic acid converts the curd into a more or less plastic condition, in which the particles adhere readily to each other. The acid is probably one of several agents which unite in preparing the curd for the press. It also shows the presence of the lactic acid ferment, and thus indicates the absence of the objectional putrifactive and gas producing germs

BUTTER FAT AND BUTTER—MELTING POINT OF BUTTER.

Will you please give the average amount of butter fat your butter maker takes to make a pound of butter of 82%, and what is the average melting point of the butter?

Opunake, New Zealand. W. P.

It depends on the source of the butter fat. If in the milk, one pound of fat will make, on an average, 1.17 pounds of butter. In actual practice this may vary several per cent above or below this figure, depending on the amount of water left in the butter after working, and the losses which occur in separating and churning. If the fat is in the cream, the yield will be between 3 and 4 per cent higher than the above.

The melting point changes slightly, according to the food and period of lactation, but the average is 96° F.

RYE HAY.

I have a field of rye and want to know how is the best way to care for it to feed to cows, when to cut and how to keep? What kind of feed will corn make cut green into the hay mow instead of silo? Do not the Biltmore people save corn crop this way?

Palmyra, Mo. G. V. S.

To obtain the best feeding value of rye when made into hay, it should be cut just as it begins to bloom. At this time it contains its maximum of nutrition and is in its most palatable condition. As a feed it ranks a little above oat hay, in analysis. Rye has been used in the silo, but without any great success. The stalk grows woody rapidly after blossoming and that, in connection with the hollow stem, renders it liable to mold and spoil to a large extent in the silo.

We do not know what the custom is at Biltmore, in handling corn. But it is certain that green corn cut into the hay mow would be better fitted for the manure pile rather than a cow feed, when it came out keeping green corn successfully depends on its being kept in an air tight space, whereas a mow would be just the opposite.

SALTING AND WASHING BUTTER.

Please tell me what is the most modern plan of making butter. How much salt per pound; also let me know if it is best to wash it? If you cannot answer, kindly tell me of some book devoted to butter making.

Cocoa, Fla. A. L.

Our correspondent asks a question that would require more space than is permissible, to answer, fully. The most satisfactory way for him to do, is to obtain "American Dairying," by Gurler, and "Milk and Its Products," by Wing. They can be obtained at this office for one dollar each, post paid.

The amount of salt used is between ¾ to 1 ounce per pound of butter. The salting is much lighter than formerly, and the trend is towards a lightly salted butter.

One washing is sufficient, although some good butter makers do not wash at all. The advisability of washing, depends on the market. Well washed butter has less flavor, but will keep longer than the unwashed.

PARA GRASS AND TEOSINTE.

You would oblige me by giving, through the columns of the DAIRYMAN, the analysis of the Teosinte which obtained high honors in the Chicago World's Fair, and of the Para grass, which grows abundantly in Jamaica, and most parts of the tropics.

Guatemala. J. MONT..

The analysis of the two plants is as follows:

	Fat.	*Protein.*	*Carbohydrates.*
Teosinte	3.1	7.3	81.4
Para grass	1.27	8.06	71.86

The above is the analysis of the air-dried material, and of course does not show the digestibility of the several nutrients.

SWEET CURDLING OF CREAM.

I would feel much obliged to you if you would give me cause and remedy for cream loppering in a few hours after being separated, while it remains sweet. After a day or so gets lumpy, and has an unpleasant taste. The cream separated in the evening is worse than in the morning. Cows are on pasture, where there was clover and timothy last season. F. D.

Baltimore Co., Md.

Sweet curdling of milk or cream, is due to a class of bacteria which sometimes get the upper hand of the normal lactic acid germs, and cause a fermentation without the formation of acid.

The curds produced by such bacteria are quite different in appearance and taste from the normal sour milk curds. There is no sour taste and the curdling is more rapid than in the case of the regular lactic acid fermentation.

On being allowed to stand the sweet curds undergo a digestion or solution of the casein, forming jelly like lumps and turbid whey.

The class of germs which cause the above condition are very resistant and hard to get rid of, and in some cases have been known to resist a continuous application of steam for six hours. The germs are found in dust and dirt and more especially in mud holes, from whence they are easily transferred to the cow's udders, and thence to the milk pail.

To get rid of them, see that everything connected with the cows and dairy is thoroughly cleaned; keep the cows out of any mud holes, where they may become muddied and thus act as carriers of the objectionable germs.

Finally, as these germs are sensitive to the presence of acids, set up a germ war, by the use of a good, strong, clean, lactic acid starter; until you get the upper hand, and your cream becomes normal again.

Thorough cleanliness and the use of a good starter will get rid of the trouble.

More About Which Is the Better Cow.

Inquiries. Answers. Criticism.

We have the pleasure of submitting below three communications, looking to a solution or explanation of the reasons why so large a proportion of the answers in regard to the two Guernsey cows were erroneous.

The first is a series of

PERTINENT INQUIRIES.

ED. HOARD'S DAIRYMAN:—I am like the man who, when told that facts did not support his theory, replied: "So much the worse for the facts.

Now since we have entered upon a discussion of those two cows, let us learn all that we can about the whole subject.

How do the two cows compare in size?

How long was the previous period of lactation of each and how long did each go dry before the record?

At what time during the record was each one bred again?

What is the form and character of the escutcheon of each? I will guess that Rose's is something like No. 1, and that Gem's is more like No. 2:

I confidently expect that the answers to these questions will justify the decisions of us eight to one.

Michigan. W. C. HUNTINGTON.

Pending the arrival of the full and courteous reply from Ellerslie Farm, we received the subjoined communication from Mr. Donaldson of Nova Scotia, wherein he very justly sets forth some of the invariable difficulties connected with

JUDGING COWS FROM PICTURES.

ED. HOARD'S DAIRYMAN:—Your interesting discussion lately as to which was the better cow, Villet's Gem or Rose of the Quartiers, reveals some important facts to me as doubtless it will to a good many of your other readers.

I must first congratulate you on the new departure which this discussion has brought about. I really think it most important for readers of our agricultural papers to take part in discussing different topics and especially so when the editors bring about such important discussions as the above.

Of course we must all make some allowances for pictures, for no picture can fully show a cow as she really exists; still we can get a fairly good representation by them. This judging of dairy cows has been particularly interesting to me as the result of this competition seems to confirm my views on this subject, viz: that it is extremely difficult to judge dairy cows merely by their external appearance.

In common with the majority of your readers, I too think I should have given the preference to Rose of the Quartiers, as being the better cow in her general make up and dairy conformation. Yet in view of their actual records during the past year (supposing they had had similar feed and calved about the same season of the year) I would undoubtedly pay the higher price for Villet's Gem as a dairy cow, and I am doubtful, Mr. Editor, about your suggestion that they may reverse these records another year.

I have kept a milk record of my cows for some years past and I think I could successfully defy any dairy judge to come into my stable and place my cows as to their actual milk yields. Now, why should this be so, if our system of dairy judging be altogether correct and the so-called dairy conformation be all that is necessary?

Why should not a good dairy judge be able to pick out the best cow in every stable? Simply because I believe there is a certain individuality in cows—call it will force or nerve power or whatever you like,—some inherent living power that marks the individuality of cows.

No two cows are just alike, no matter how similar they are made. How ridiculous to compare a living dairy cow to an inanimate lifeless machine, and yet that is what we are constantly hearing and being taught in dairy literature and in exhibition show rings!

See how most of your readers were deceived in "Villet's Gem" and "Rose of the Quartiers", and yet the former gave 925 pounds more milk. And is not the same judging carried on at all of our show rings, dairy conformation being the sole standard of judging?

Exactly the same as buying a cook stove; you pick out one that looks as though it would serve your purposes the best—that will bake well, that is the most convenient shape, that will probably be the most economical in fuel, etc. There is no living force to be taken into account, no capricious appetite to be looked after, no health to be preserved, no likes or dislikes to be taken into account as there is in a living dairy cow.

What would you think of hiring farm laborers just from their external appearance?

Do you think the best built man physically, even generally performs the most labor? I think not. Now I should say there was more similarity between a cow and a man than between a cow and a stove.

Don't misunderstand me. I believe in dairy conformation, but I do not belive it should be the sole standard of judging. Neither do I think we should judge cows exclusively by their actual milk products. But I do believe in breeding only from what is considered the best dairy shaped cow, provided her actual milk yield is also satisfactory, or up to a certain standard.

In no case would I breed from a cow, no matter how perfect her dairy shape, provided her actual milk yield was small. Should not this be more the standard of judging in our exhibition show rings?

JOHN DONALDSON.

Port Williams, N. S.

We quite agree with the general propositions submitted above, and indeed, on more than one occasion, have expressed similar views. There *is* "some inherent living power that marks the individuality of cows," and differentiates them from insensate machines. With the living animal before us, to be viewed from all sides, and her every motion and pose considered, we can gather some hints as to this temperament, that do not show in a picture and more particularly in a photograph.

Pedigree (which is but another name for breeding), and training have much (possibly everything) to do with the origin and development of temperament, but nature is constantly striving to adapt form to function, and hence form becomes the most reliable index to function. We may never be able to judge from form, which is the better of two cows, when one yields 608 lbs. of butter in a year and the other 548 lbs., or detect other *ten per cent* differences, but it by no means follows that form is unimportant, or that we should omit to study its meanings.

And, as we have stated before, it is by no means certain that future records may not justify the majority opinion that Rose of the Quartiers is the better cow. In 1898, she increased her previous butter record by 232 lbs., whereas Villet's Gem gained only 156 lbs. And yet it is to be confessed that her suspicious disposition and the lack of room for a wide, square udder" detract somewhat from the probability of such a result.

The foregoing was referred to Ellerslie Farm with request for as full reply as could be given, not only to the specific questions, but to the general condition, form and temperament of the two cows. Following is the

ANSWER:

ED. HOARD'S DAIRYMAN:—Yours of June 6th, referred to me for data concerning Imp. Villet's Gem 8664 and Imp. Rose of the Quartiers 8654.

Imp. Villet's Gem, dropped her first calf about the time of arriving in quarantine or April 19, 1895 and arrived at Ellerslie about July 5th or 6th, so will not give you record until after she did a year's work.

Her record for the three subsequent years is as follows:

Year	*Lbs. Milk*	*Average Test*	*Lbs. Butter*
1896	5,566	5.62%	394
1897	7,406	5.19	452
1898	9,265	5.58	608

The amount of butter is estimated on the basis of 85 lbs. of fat in the milk making 100 lbs. of butter.

Villet's Gem dropped a calf each year and was a very continuous milker, having been dry this year less than one month.

Imp. Rose of the Quartiers calved March 12, 1895, and arrived in quarantine in April She had her next calf April 15, 1897, and another March 2, 1898. She is now dry, expecting her to drop a calf about July 27, 1899. Her record for the three years is as follows:

Year	*Lbs. Milk*	*Average Test*	*Lbs. Butter*
1896	4,746	5.22%	891
1897	5 676	4.73	316
1898	8,334	5.59	548

Her yield of milk for one month was 1,079 lbs., against 1,540 for Villet's Gem

In disposition, both cows have a nervous temperament, and yet are different: Villet's Gem has confidence in her master and is appreciative; rather looks to you for protection; while Rose of the Quartiers is more excitable, always looking for something to happen. Yet both these cows have had kind treatment for the past four years.

As to milk veins, Villet's Gem's are far superior, she has a better navel development also. Rose of the Quarters has the best fore udder, but she lacks width across the huckle, so there is not room for a wide square udder, such as we would like to see. This, the picture does not show.

As to size, Villet's Gem weighs about 900 pounds; Rose of the Quartiers 1,050 pounds.

They were each bred to drop a calf about once a year, but Rose of the Quartiers was the more difficult to get in calf; as you see it was a trifle over two years between 1895 and 1897. She had her last calf March 2, 1898, while Villet's Gem calved March 21, 1899.

Mr. Huntington has drawn the general shape of the escutcheons quite as they appear. F. E. TRAVER.

Ellerslie Farm.

WHAT THE FARMERS'S BOY SHOULD KNOW TO ENTER AN AGRICULTURAL COLLEGE.

A young man made the following inquiries concerning the amount of education necessary to take up a course in some agricultural college. Prof. I. P. Roberts answeres him as follows:

I am a young man 23 years of age and am working on a stock farm. My desire is to climb to the top of the ladder in the agricultural world. I am preparing myself for a course in the agricultural college and would like to know what books would be best for me to get to read up on, prior to my entering college next year. I have Henry's "Feeds and Feeding," and several other books from different states: also receive farmers bulletins from almost every state in the union.—H. H., Otsego County, N. Y.

Answer by Prof. I. P. ROBERTS.

If H. H. proposes to come to Cornell University to study agriculture, he should try to perfect himself in the ordinary branches and as many advanced subjects as possible. Specific instruction in agriculture should be taken here; and while Prof. Henry's book is most admirable, it can not be thoroughly understood and appreciated without the aid of a living teacher.

We find our students are mainly deficient in two things—English and arithmetic. If a student proposes to enter the regular or four-year course, he must have had somewhat extended and careful training before he enters the university or he will not be able to carry his advanced studies while here. There is not nearly enough stress laid upon the preparatory work. Nearly all the young men who desire to take either the four or the two year course, want to take agriculture first in their course instead of preparing thoroughly for the work and then taking it up later when they have some idea of chemistry and botany, and of what accurate and careful work means.

A progressive young man who cannot find time to fit himself for university work or time to spend a few years in study at a college or university should depend very largely for his instruction on the best agricultural journals. He should have a few books of reference and the bulletins, but these can never be made to take the place of the live, current literature contained in a good journal devoted to rural affairs. Nearly all of these journals now have on their staff a considerable number of trained specialists to whom queries are referred, the answers to which are usually by men thoroughly honest and fully competent. True, it is not possible always to "hit the nail on the head," because the query, of necessity, does not state all the conditions; but I want to emphasize here and now that while some half a dozen books of reference and bulletins are invaluable to the home student, yet they cannot and should not take the place of the weekly agricultural journal.

If H. H. comes to Cornell University and enters any of the agricultural courses he will be met immediately with percentages, fractions, etc., and will be called upon to exhibit his skill in the use of the English language; and since there is little time here to perfect the carelessly trained student along these lines, he should devote his entire time to what is termed the "primary subjects," brighten up, that is, renew his knowledge of arithmetic and grammar. He can get his chemistry, botany, etc., after he arrives at the college, and it is presumed he will have better teachers and equipment at a college than he can find at a high school.

The above answer by Prof. Roberts shows how fearfully deficient our country schools are in teaching the rudiments of an education. Take that one sentence—

"We find our students are mainly deficient in two things, English and arithmetic."

Hundreds of bright farm boys can be found who are good butter makers in a creamery, but comparatively few of them can figure in percentage sufficiently well to properly and accurately make out the dividend for the patrons.

The Short Course boys who present them-

"The Least Hair Casts a Shadow."

A single drop of poison blood will, unless checked in time, make the whole impure. Hood's Sarsaparilla is the great leader in blood purifiers.

selves at Madison or Cornell, find to their mortification very often that their arithmetic is so poor that they are barred further progress. The country school is a farmer's school. It is the farmers who are responsible for it, and the kind of teaching that is done in it. What the farmers about it are that will the school be.

It is time that American farmers woke up to a right sense of the cheap, miserable character, in most cases, of the average country school.

Cream Ripening.

[Paper read at the National Buttermaker's Association, Sioux Falls, South Dakota.]

The subject upon which I am to talk a few minutes is a very small one, small because it is something of which the least is known of any part of the science of butter making.

The idea largely prevails that flavor in butter is caused by the way the cream is ripened, providing, of course, that the milk and cream has been handled properly previous to this. If I were able to lay down some definite rule in regard to ripening cream, which, if followed, would bring about the same result every time, then I believe the mysteries of this hidden secret would be revealed, but there is no such rule, no dairy professor or dairy student has been able to tell us how to ripen cream so that we might be sure of the same results two days in succession.

We may be lucky, if you will allow the term, and win the sweepstakes at a convention, but the next time we make a convention tub, by using the same temperatures, the same acidity, and all other parts of the work exactly the same, we find a vast difference in the quality of the butter. Why is this? This is the great question which I am unable to answer. If we only knew, the process of ripening cream would be very simple.

To make myself more clear on this point, I will illustrate: My patrons, for instance, bring in twenty thousand pounds of milk one day, which, after a careful examination, I pronounce of superior quality. I manufacture this milk into butter according to the best improved methods and with good results; an expert scores it 98½. The next day the patrons bring in twenty thousand pounds more, and, after the same careful examination, I find this is equally as good as the day previous. This is also handled just the same as the milk received the day before, but with far different results. The expert scores this 92.

Where does all this difference come in? Is it my fault? Or is there some unseen force working in this milk, of which I, or no one else, has any knowledge? For the sake of argument, I believe the latter theory is correct. The unseen force is the bacteria, which the scientists tell us is in all milk, and, until they can give us some method whereby we can tell just what action they will have on the cream, the ripening of cream will remain one of the dark mysteries which abound throughout this life.

Of course there has been very much light thrown on this subject; we know a great deal more than we did years ago. We have found out that to develop a certain amount of acid will give good results. We have also found that, with some cream, a different temperature will give better results than others.

We have also learned that starters, (providing that they contain the proper germs) will improve the flavor of the butter. But this is about all the new things which we have learned in regard to cream ripening. Therefore, as I am unable to tell you of some new method which I have discovered that will throw the dairy world into a fever of excitement, I will give you my simple method of ripening cream, which has been very satisfactory to me and has brought good returns to my employer. Remember, this is not the only way to ripen cream, for if the question, "How do you ripen your cream?" was asked every buttermaker present, they would probably answer it in many different ways, and each one has had splendid results from his own particular method, so, as I said above, it would be useless for me, even if it were possible, to lay before this audience any set rules for ripening cream that would produce the best flavored butter.

My first thought towards cream ripening, is that of a well prepared starter which is made from skim milk, selected from patrons having fresh cows. Patrons that can be depended upon to take the best care of their milk.

After it is delivered to the creamery, I run it through the separator, as I believe that a starter made with the butter fat taken out is better than that in which the fat is left in. I set this milk away in a fermenting can, and leave it at a temperature at which it will develop a sharp acid, and a pleasant flavor, by the next morning, when it is added to the cream.

I wish to impress upon the buttermakers present that this is a very particular part of their work, not all milk that is received at the creamery is fit to make a starter; and if a starter is made out of poor milk the chances are that the whole day's cream will be injured. So I would advise you that unless you get perfect milk to prepare your starter from, it would be better not to use any at all.

I am a firm believer in starters in ripening cream, and I do not hesitate in saying that thousands and thousands of dollars have been lost which could have been saved, if the butter makers had had a thorough knowledge of preparing starters and using them.

The cream should be skimmed very heavy, and I believe that about thirty per cent fat is about right, for this will give the starter all possible chance of filling its mission. Now there are many buttermakers who use starters, but they get no good results for the reason that they do not use enough.

It is useless to use less than fifteen per cent, winter or summer, and I should prefer twenty, especially in the winter time. I have obtained the best results when the cream was kept at a temperature of sixty to sixty-two degrees until it commenced to thicken, and then cooled down to the churning temperature, say fifty-two.

I have also found that there is a certain time which the cream is churned at the best flavored butter can be made. There is no time before or after this when the results will be as good as at this certain churning time, so I would advise you in conclusion not to depend upon your own judgment to determine when this certain time is, but to use some sort of an acid test which will show you exactly how much acid your cream contains, and then when you ascertain what degree of acidity gives the best results, do not change your methods, but keep it the same at all times.

Comments and Queries from Robinswood Farm.

The Ventilation of Cow Stables.—Antiseptic Injections.—Cold Applications for Udder Inflammation.

ED. HOARD'S DAIRYMAN:—The need of thorough ventilation in cow stables is, of course, of the first importance. Purity of the air breathed is necessary to insure the best of health in cows as well as in man. The vital energy thus secured is one of the most potent preventives of tuberculosis and in inducing an active profitable function in all of the organs working for man's profit in the cow.

A neighbor of mine, whom I consider the most intelligent dairyman of our region, purposely left half inch cracks in his barn boarding on the south face, and did not board in his tie-up, simply to secure this healthful condition for his herd of pure bred Jerseys. He preferred to feed more food than to shut out fresh air and run the risk of tuberculosis. This disease, however, is uncommon on our Gilmanton hills, which are as noted for healthfulness as they are for their rocky soil.

Nevertheless, one should not neglect the matter of ventilation, because one's cow barn is in an exceptionally healthful locality. There are a number of methods of securing this aim and yet keep the cows comfortably warm.

The system lately shown by Prof. King in the DAIRYMAN, from a theoretical point of view, seems to be open to criticism in that its working is somewhat in opposition to natural forces. It may be allowable to criticise any plan which is based on the assumption that the carbon dioxide exhaled from the cow's lungs settles to the lower level of the stable, and that hence, flues which take their inlet from near the floor line should be provided. Such provision is not needed. As a matter of fact, the expansive, diffusive force of all gases in connection with its heated condition as it comes from the cows' lungs prevents any such settling and accumulation of carbon dioxide, and these forces can be depended on to carry off this gas from openings at the top of the stable.

Again, the presence of this gas in reasonable amount is not particularly injurious, as it is always a considerable constituent in all animal bodies. Furthermore, there are certain organic effluvia and emanations from the lungs and body which are relatively more injurious and devitalizing to health and which are found mostly in the higher strata of the apartment occupied, and which it is desirable to get rid of without re-breathing.

Then it does not seem a good plan to introduce the fresh air from behind the cows, on account of the draft produced over their bodies. This cools off the bodies of the cows unnecessarily, and this is particularly objectionable where the surface of the udder is concerned, in the tissues of which a high temperature is needed to secure the greatest activity of function.

If it were practical to heat the incoming air by a line of hot water pipes located against the barn wall at the rear of the cows, there would be no such objection; but it is at least questionable if such an arrangement would ordinarily pay, and is out of reach of the average farmer. When the warmth of the cow stable is dependent on the heat produced by the cow, it would seem best to introduce fresh air as near the nostrils of the cow as may be possible, and then carry off the effete respired air in flues or otherwise, as directly as possible at a point above and not too far from the cows' heads; leaving the bulk of the air in the tie up and surrounding the cows bodies as little disturbed by air currents as possible.

In this way it would seem that the greatest amount of fresh, pure air could be enjoyed by the cows with the least expenditure of heat created by the cows.

The particular means for securing ventilation must, of course, vary according to the structure of the cow stable.

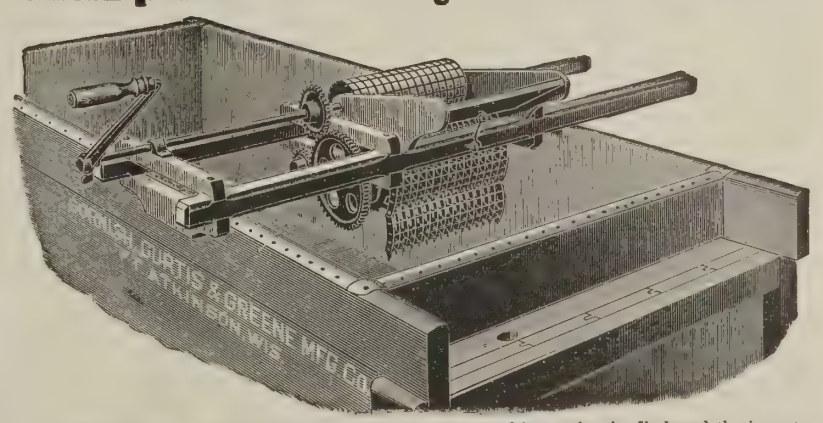
In the usual New England barn, which has a large middle driveway with abundant openings to the roof, with a hay bay on the coldest side and the low-ceiled tie-up on the warmer side, the problem is quite easy. The interior of the barn is freely ventilated through the innumerable crevices in the high roof and from the crack of the large doors.

If, now, the low Stoddard tie-up is enclosed along its front with a stationary middle section and two sections hinged from the upper and lower edges of this middle section, and not too closely jointed, we get ample arrangement that will keep a warm stable and yet secure any desirable degree of ventilation. The fresh cold air from the driveway enters the crack of the lower hinged section at the floor line, is breathed by the cow and finds its way out at the crack of the upper hinged section, at the level of the top of the tie-up.

There are newer styles of cow stables than the old-fashioned New England barn, but I have never seen one that to my mind offers so many practical advantages. Even the manure cellar under the tie-up does not seem to be objectionable in cold climates, while it offers unexcelled advantages for convenient disposal and economical storage of the droppings.

Has any experimentation been made in regard to heating cow stables with hot water or steam? If so, I, and probably others, would be glad to know of them. In regions of cheap feed and high cost of heat producing feeds, it is a possibility that to maintain a proper temperature in a cow stable, it may, under some circumstances, cost less with such heat than with cow feed. In any case the pure air for breathing is an imperative necessity.

In this day of antiseptic precautions, it seems that harm may come to the dairyman from meddlesome interference with the natural means of protection previous to and during the parturition of the calf, as it frequently is during the birth of human children. It is only lately that it has been announced that the natural secretions of the parturient canals in woman are in themselves antiseptic, and hence injections of antiseptics are usually likely to do more harm than good. It does not seem good practice to syringe out the vagina of the incoming cow unless there is evident necessity for doing so. One may infect rather than disinfect. It should be borne in mind that any agent that will kill disease germs will also have more or less damaging effect on the protoplasm in the cells of the higher animals. Such agents are not to be used except as a necessary evil, and only in the light of an evident need.



Is there any reason why applications of cold water should not be made to the udder of the cow in case of inflammatory affections of that organ? One continually sees in print, recommendations of rubbing of the bag in such cases with or without oily substances. The latter is evidently used to prevent heat, the rubbing producing undue friction and heat at the surface. Of course, massage of the organ tends to dissipate congested areas where the blood is engorged, but certainly the practice is accomplished with more or less bruising and irritation of the inflamed parts.

Reasoning from generalities, it would seem that the free applications of cold water would tend to reduce inflammation by shrinking the blood vessels and reduce the irritability in the parts. Is there any counter reason for not doing this? Rest and cold water are powerful remedial agents in the treatment of human beings. Why not in the cow?

New Hampshire.

Kasper Rotary Curd Mill.

The demand for a large capacity curd mill for cutting curd into cubes has induced the inventor to bring out the Kasper Mill. In construction the mill consists of a rotary cylinder made of knives in the form of cubes. Against these knives a wooden roll revolves with indentations to fit the knives of the cylinder; the curd being fed into the hopper is forced through the openings in the cylinder by the wooden roll. The cylinder is made in three sections hung on hinges, and, as it revolves, each section as it comes to the lower part of the cylinder, opens and allows the curd to drop into the vat, the section closing again as the cylinder revolves.

It is estimated that the curd from 7,000 lbs. of milk can be cut in from 7 to 10 minutes The mill operates easily, being light running and adjustable to either hand or belt power. Simplicity of construction, durability and ease of cleaning are some of its principal features. All parts being galvanized or tinned prevents rusting. Weight of the machine complete is about 38 pounds. List price, $25.00.

Farm Dairying.

As far back as history extends, the cow and her products have been one of man's best friends. And from the time when the cream was tied up in a skin and laid across the camel's back to be churned into butter, to the present, with all its modern appliances, butter has been one of her staple products. And when we look at some of the dairy butter on our markets to day, we wonder if the butter of twenty centuries ago could have been much worse.

We are standing to-day, when to do anything at a loss, means not only empty pocketbooks, but brings lines of care, and thought how to fill the vacuum with the dollars so much needed to carry on the world's mighty advances, and keep ourselves in touch with its every day life. And often times, to use the old house wife's adage, we are throwing out with a teaspoon faster than we can bring in with a shovel.

Each and every one of us know to a certainty that we make the very best butter it is possible to make, and we all are apt to cry out at the great injustice done us because A or B get more for their product than we do. Go into a country store to-day after the usual closing of the cheese factory in the early winter months, see the conglomeration put on the market as dairy butter, not two samples alike, not two of the same flavor or color, one as white as lard, another as yellow as a sunflower, another all colors mixed, and all classed under the same head, dairy butter, for which the merchant is supposed to pay the same price. Some will go as extra, some will go as fair, some will go for shortning, more will go as grease.

One has spent the same toil and labor as the other and thinks his should have the same pay. The merchant is not the only loser. They have wasted their time and funds in an almost unmarketable article and the good and bad go under the same head, dairy butter. And when we know that the whole might, with the same labor and work, have been a good article, and when we know that the farmer's wife must, in the general run of things, be the sufferer, we feel we must lighten her burden in some way.

We cannot all of us be as quick as the Kurrian woman, in a Dakota town. The merchant did not want to hurt her feelings by telling her it was impossible for him to use the product she had brought him in her wash tub in great rolls and called it butter, so he told her it was impossible for him to take it as the market called for little rolls, he could not sell the big ones, down went the wash tub on the floor, and up went her sleeves, and with her hands she made the butter into little rolls, spread them on his counter and when done said, there it was as he liked it, she had done her part, necessity compelled him to do his.

Could I change the work of the ordinary home dairy as easy, I would feel it were time well spent. Do not, by this paper, understand me to say that farm dairying is the best way to solve the question. But as long as we do or must have them, let us make its product the best there is to be made and get all there is in it. I do contend this, however, that a well conducted farm dairy, with only one herd to get its milk from, should and could make better butter than the best regulated creamery.

It is no harder work to make it good than it is to make it into soap grease, and the difference in price is much in favor of the good. The farmer who makes poor butter, will, as a rule, have poor cows; not, as a rule, properly fed or cared for; you cannot get much butter fat out of barley straw, as one man found to his sorrow the past winter. Fed as many of our cows are, which furnish the greater portion of store dairy butter, they yield a small amount of butter fat, and with the poor appliances used in getting the fat, they get a very much smaller return for their work than they would otherwise. Consequently the poor cow is blamed for the failures.

There are some few things indispensible to perfect farm dairying: Cleanliness, plenty of good water, a good churn, good cans, those that can be submerged (if one cannot afford a good separator, which has been proven without a doubt the best way now of handling milk) and a good air tight cream vat, not too small, so as to give room for regulating the temperature of your cream, a thermometer—nothing necessarily expensive. Besides the separator in these days of advanced farming, there is an article that is almost indispensible to any farmer, who handles milk, either for creamery or cheese factory or private use, and it will eventually save many a dollar to the farmer, as well as to the cheese factory and creamery, and that is a good, first-class aerator. Many a milking is lost to the farmer without it, which would far more than pay the first cost, and did I have to set milk without ice-water, I should certainly use one.

When we say "cleanliness" we do not mean simply after the milk is brought in from the barn. It is as necessary that it should be clean before it is strained, as after. Could you see the inside of a separator bowl, as I do every day, you would realize what this means, and that, too, after the milk has been strained through five thicknesses of cloth. It is often enough to turn one against the thought of milk even to see the inside of one of these bowls. So use plenty of hot water and a little borax or lye about all dairy implements, as it takes a very little thing to make a bad flavor in butter.

In submerging milk, keep the water perfectly clean and as cold as you possibly can. Don't think that once a week is going to do. Nothing, it seems to me, gets foul so quickly as water that has had cans of milk or cream standing in it. You should pump it in fresh every day, especially if you do not have ice, if you do not want from one to two per cent of butter fat left in your skim milk.

Now many people think that anything that will bring butter out of cream, is a churn; consequently there are more inventions in the patent office, at Washington, to make butter on the farm, than any other device patented. There are only about three kinds of churns that a farmer can afford to use, if he wants to make the very best butter, and you are all well aware that we do. There is the barrel, the box, and the rectangular box, hung by the corners. Butter, to churn properly, must come in the granular form, and must be thoroughly worked and salted in this form. It is impossible to do this in any small churn with inside apparatus.

To make good butter, keep your cream sweet until you get enough for churning, then from eighteen to twenty-four hours before churning thoroughly mix, and let it stand until sour, not simply until it tastes sour, but until it gets a little thick. Don't put in any cream later than eighteen hours, or you will have a part in your buttermilk.

Churn in summer at a temperature of about 58° to 60°, not higher, if you churn by hand, if with a power churn, as low as 56°. Churn until it will separate from the buttermilk in small granules, from a portion of your buttermilk; then pour in from two to four pints of good, cold water, according to the size of your churning; put your cover on, turn rapidly a few moments, run this water off and repeat the operation.

Have your water as cold and fresh as possible in summer, and if you have ice and want your butter solid, use ice-water. Run the last water off as dry as possible; then to every ten pounds of butter use a heaping pint bowl of salt, the best fine dairy salt; now rock your churn from side to side, gently, to thoroughly mix your salt; then put on your cover, turn gently until your butter is in good, solid lumps.

In summer when it gathers into large lumps, take your spade and open up the lumps and repeat the operation two or three times, and you will have your butter in fine condition without any butter milk or any streaks, ready to pack in your tubs or jars for market. Streaked or mottled butter is caused by churning a little too long, so be very careful not to churn only to the granular form; little too large grains or a little gathered water prevents the salt from acting quick enough to go through the lumps, causing the mottled appearance, which requires tough working to get out and spoils the grain of your butter. Do not fail to use a good color in your butter, a small teaspoonful to ten or twelve pounds of butter is about enough. The market demands it, and the color alone will often decide a party on the taking or letting alone of a jar of butter.

We must fill the market demands if we wish to get the top market for our products. Have a spade and a small packer like a good sized potato marker to pack with; see that it is packed solid all through the jar. We can only make a success of it by making the very best. The time is surely coming when the merchant cannot afford to barter for good and poor butter alike, and he cannot afford to have the small balance on his side of the ledger.

The farmer must stand the consequences of his own faulty make, and cows that will not yield you 40 cents a hundred for the milk the year through are unprofitable servants, to you farmers who are forced to buy your butter, and whose milk is bringing a good round sum at the cheese factory.

Don't complain because you are paying the market price for a good article. Remember if your milk goes down you are the first one to grumble, and your butter farmer is but as much entitled to his pay, for an honest article, as you are, and when your milk is bringing a good price you can afford to let the others have it too. Let us all live and let live; we cannot afford to grumble. Our farmers can only be made to produce what we make them do. The man who makes two blades of grass grow where one grew before, is a benefactor, and what we do, let that be the best. *

The above article was received without name or address, but it contains too many well put truths to permit it to remain unpublished in consequence.—ED. DAIRYMAN.

Butter Making in Holland.

There are two methods of making butter—the old and the new. The first consists in setting the milk in earthen pans about four inches deep and sixteen inches in diameter. But owing to the bad system in handling the milk, it being left so long in the cow house, the excessive temperature and also defective arrangements, it quickly undergoes, especially in summer, a fermentation which causes precipitation of casein and naturally prevents formation of cream. Thus the farmer makes butter and cheese at the same time. The butter thus made has a bitter and unpleasant flavor, caused by the decomposed casein. However, when the cream has risen, it is removed and churned just as it is; another inconvenience appears while churning. The cream and buttermilk are sour, which, from a technical point of view, is something to be avoided. Besides, as during churning the requisite temperature does not always exist, formation of butter is generally very slow and sometimes there is none whatever. In a word, butter made by this system is generally of inferior quality and has an unpleasant flavor and odor; it is also wanting in consistency and does not keep.

The second method, as we shall see, is the only one which gives satisfactory results. Steam butter dairies, where milk is creamed by the aid of centrifugal creamers, have made a great improvement in the manufacture of butter. The following is the system of work: First of all the milk is heated, and as soon as the cream has been removed by the centrifugal creamer it is allowed to cool and is then poured into metal cylindrical vessels, where it is left for twenty-four hours to turn sour. These vessels are kept in coolers. Churned milk of the previous day is employed as a ferment, but this last causes the same inconvenience as the first method. Consequently buttermakers obtain milk churned in another dairy. At the end of 25 hours the cream is churned, the butter is washed and salted, and, 24 hours later, kneaded. Kneading is the last manipulation. The butter is retailed in lumps of 2¼ pounds, either wrapped in special paper or in stone jars. It is sold wholesale in wooden tubs weighing 44 to 88 pounds, in half or quarter "vaalje," according to the native term.

There are three kinds of butter—fresh, salt and melted. The first on leaving the churn is well washed in water, either by machine or hand, to remove all the buttermilk. For salting there is a special machine, in which the butter is kneaded with sea salt in the proportion of 1 per cent. In Limburg, butter made by farm buttermakers generally goes to market unsalted; butter from the co-operative dairies is salted. No melted butter is made in the Netherlands. The production of butter in the provinces in 1895 was 24,560,520 pounds. To this must be added 66,201,249 pounds of farm butter and 72,188 pounds of dairy butter.—*Ex.*

Food or Breed.

The quality of the milk depends upon the fat in it, and the fat either depends upon the quality of the cow, or the food given to it. There are plenty who believe that the quality of the milk can be changed by changing the food. That is, certain kinds of food make milk rich in fat, and other foods make milk poor in fat. The question of which is correct is interesting to dairymen, and if it is the food that determines the question, they want a ration that will give the best results

Most farmers have been led to believe that the percentage of fat in the milk is determined largely by the quality of the food given to the cows. On the other hand, the results of nearly all the scientific experiments and tests go to show that the kind of food fed to the cow has little influence upon the fat in the milk, but that everything depends upon the cow. There are some cows that seem to be born with the ability to produce milk rich in fat, and food of any kind will keep up this supply. Of course starving and gradual degeneration of the animal will decrease the supply of milk, and consequently the quality of fat. But with fair care and food the percentage of fat will remain good and quite constant.

This brings us to the important matter that all dairymen must consider. The cow is a law unto herself. She is created a milking machine that is valuable to her owner, or she is a poor milker whose existence on the farm is unprofitable to the farmer. Experiments conducted in the most careful manner have failed to increase the fat of a cow's milk to any material extent. Under forced feeding the fat percentage might be increased, but it would only be temporarily. Some seasons of the year the percentage of fat is much higher in one cow's milk than at another time, and the change should not be attributed to the food. It is due to natural causes that cannot easily be explained. So we come to the conclusion that while breed and the individual cow may not be everything, it certainly is more than half the question. Food plays an important part in keeping the cows up to a standard of health and functional activity, but its influence is comparatively small in determining the quantity and quality of the fat in the milk. The moral is very obvious. If we expect to have good milkers, we must select cows that have a special gift for this. E. P. SMITH.

Ohio.

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—The offering of butter on Monday's Elgin Board of Trade aggregated 22,260 pounds. All bids were at 18 cents, and all sales at this figure. The market was reported firm at 18 cents. The sales reported were as follows:

Factory.	*Pounds.*	*Price.*	*Amount.*
Triumph	1,200	18c	$216 00
Red Clover	1,800	18c	324 00
East Burlington	600	18c	108.00
Evansville	6,000	18c	1,080.00
Big Foot	2,100	18c	378 00
Spring Prairie	2,100	18c	378 00
Dundee	2,100	18c	378 00
Cobb	2 700	18c	486 00
Highland	1,980	18c	354 40
Elkhorn	1,620	18c	302 40
Total	22,260		$4,004.80

The sales for the corresponding week of the three preceding years were as follows:

June 20, '98. No sales. Market price 16 cts.
June 21, '97, 43 980 lbs. of butter sold at 14½ cts.
June 22, '96, 117,900 lbs. of butter sold at 14@15 cts

The New York market, Monday, was reported steady at 18¾ cents. H. C. B.

Elgin, Ill., June 19, 1899.

Salicylic Acid in Milk.

Dr. Henry Leffman, of Philadelphia, a prominent chemist of that city, recently stated that many diseases of infants, which occur during the summer months, may be induced by the use of milk, and artificial foods which contain salicylic acid. He stated that the drug had an enormous and increasing sale, and that several forms are being put upon the market. Speaking of the artificial form used by brewers, in the preparation of bottled beer, he thought it poisonous, and that its sale should be prohibited by law. In Trenton, N. J., recently, salicylic acid in milk caused the death of several children —*Medical Times.*

This is the way a Boulder county farmer's wife treated a patent churn agent:

An agent for a new fangled churn stopped at a farm house and insisted that his churn would get two pounds more butter out of a certain amount of cream, than any other. The lady of the house, to get rid of him, told him that he could come around the next morning and try it, and if what he said was true, she would buy. In the meantime she churned the cream and when he came she poured the butter milk into his churn.

He churned for an hour and then told her that there was no butter fat in the cream. "I know it," she said, "for I churned last night and left the butter milk for you to get your extra two pounds from." And the agent was mad.—*Dairy and Creamery.*

Some months ago there was much of fault finding with certain dairymen of Minneapolis because they had fed pulp from the sugar factory, to their cows. The claim was made that while the beet pulp increased the milk supply it impoverished it in a number of respects. The department of agriculture has looked into the matter to a considerable extent and is of the opinion that beet pulp, when properly fed, is one of the best foods for dairy cattle, and beef cattle as well. The investigation made indicates the importance of the wide extension of the beet sugar industry. In its value to the farmer, it places the sugar factory alongside the creameries.—*Litchfield Review.*

DAIRY MARKETS.

ELGIN, Ill., June 19—Three hundred and seventy one tubs of butter were offered and quickly sold at 18c, the market being declared firm. Last week's price was the same; one year ago 16c; price fixed by the committee, with no sales on the board.

CHICAGO, Ill., June 19—Butter—Creamery extra, 18c; firsts, creameries, 16½@17c; seconds, 13½@14c; Dairies, selections, 15@15½c; No. 1, 13@14c; No. 2, 12c; extra ladles, 12½c.

Eggs—Fresh at mark, cases returned, sold at 11c; loss off, cases returned, 12½c; duck eggs, 11c; goose eggs, 12½c.

Cheese—Full cream, Twins, new, good to choice, 8@8¼c; Young Americas, 8@8¼c: Swiss 11@13½c; Limburger, 7@10c; Brick, 7½@8¼c.

Cattle—With 23,000 cattle, the largest receipts of the year, salesmen naturally expected to take off considerable, but the demand was exceptionally good from all sources, and in many instances light and handy steers sold at last week's closing prices, but the general market for beef cattle was about 10c, lower with heavy weights the weakest. Texas cattle and native butcher and canning stock ruled about steady. Native steers, 827@1,620 lbs, sold at 4 50@5 50, bulk 4.85@5.30; some averaging 1,276 lbs sold at 5.50; corn-fed western steers, 1,380 lbs, 5.50; fancy 1,085-lb Nebraska steers and heifers mixed at 5.40, and most of the western steers at 4.95@5.15. Distillery-fed steers sold at 5@5.10; still bulls, 3.85@4.25. About 1,100 straight Texas sold at 4.20@4.80 for steers, 4.05 for oxen, 3.65 cows, 3.25 bulls and 5.05 for 205 calves. Five loads of 1,209-lb western heifers sold at 5.05. Most of the veal calves sold at 6.85@7.05.

Bran—In fair demand and sold at 10.50 per ton in bulk, and 11.75 in sacks.

MILWAUKEE, Wis, June 19—Butter—Creamery fancy prints per pound 18c; extras, 18c; firsts, 16@17c; seconds, 14@15c; imitations, per pound, 14@15c. Dairy—Selections per pound, 13@14c; lines, 11@12½c. Market steady and trade fair for all varieties; receipts 17,115.

Cheese—American Full Cream—New, choice to fancy, 8@9c. Brick—New, choice, 7¼@8c. Limburger—Fall choice, 9@9½c; new choice, 7@7½c. Swiss—Drum, choice, 12½@13c; block, choice, 10½@11c.

Eggs—Fresh per doz 12c, loss off, cases returned. Market unchanged and active; receipts 635 cases.

AVOCA, Wis., June 19—Offerings on Lone Rock and Muscoda board to-day were 1,635 boxes, all sold at 8@8½c; market very firm.

FOND DU LAC, Wis., June 19—Offerings 575 Twins and 500 Daisies; market active at 8@8½c.

CHILTON, Wis, June 14.—The sales reported were 320 cases Young Americas at 7¾c; 170 at 8c; 160 Twins at 7½c; 80 at 7¾c; and 300 Daisies at 7¾c.

BRILLION, Wis., June 7.—Sales to-day were 1,329 Daisies and 784 Twins at 7¾@7⅞c and 324 cases Young Americas at 7¾@8⅛c. Thirty five factories were represented on the board and nine buyers were present.

PLYMOUTH, Wis., June 13—The following sales were made: 550 Twins at 7½c; 665 Twins 7⅝c; 60 Twins at 7¾c; and 820 Americas at 8⅝c.

SEYMOUR, Wis., June 13—Off rings of cheese to day were 577 Twins and 100 Daisies. Twins sold at 7⅜@7½c and 7⅝c. Daisies sold at 7¾c. Market active.

SHEBOYGAN FALLS, Wis., June 14—The offerings on the call board to-day were 705 boxes of cheese, all of which were sold as follow: Four hundred and sixty five cases of Young Americas at 8⅜c; 180 Twins, 7½c; 60 Daisies, 8¼c. The light offering to day is due to the fact that several factory men fearing a drop in the market, sold 500 or 600 boxes of cheese during the past week.

MANITOWOC, Wis., June 14—Offerings of cheese at Dairy Board of Trade to-day were, 600 boxes Daisies, 220 boxes Twins, 850 boxes Young Americas. Sales were, 250 boxes Daisies, at 7¼c; 150 boxes at 7½c and 250 boxes at 7¾c; 140 boxes Twins, at 7¼c, 150 boxes 7½c, 57 boxes 7¾c; 850 boxes Young Americas, 7¾c.

SHEBOYGAN, Wis., June 14—Sales; 538 Young Americas at 8½c; 374 Twins at 7⅝c.

NEW YORK June 19—Butter—Creamery, Western extras, 18¾@19c; firsts, 18@18¼c; state extras, 18@18¾c; firsts, 17@18.

Cheese—State full cream, large or small colored or white fancy 8¼c.

Eggs—State, Pennsylvania, and Western, 14@15c.

NEW YORK MARKET.

NEW YORK, June 17—Butter—Receipts for the week, 64,103 packages. Exports for the week, 438 packages.

Receipts from all quarters continued heavy and exports very light. During the present week there were some special creameries sold up to 18¼c and positive pronounced fine flavored, fresh, butter is still quotable at this price. Such style is easier sold at 18⅝c than the average make of creamery at 17½@18c, but it comprises only the very finest creamery make fresh from the churn, and while the price of such is quoted 18½c, the bulk of business was done at lower rates than last week. New York State Dairy of finest quality was scarce and sold readily on arrival. Sales of New York State Creameries at Jamestown and Canton this week were at 18@18½c; buyers of these goods were unable to sell at point and the bulk of it went into freezers for late markets. Fine ladle butter continues in fair demand at slightly advanced prices and is firm at the close. We quote: Creameries, extra, 18½c; medium, 17@18c; poor, 16½c. Dairies, 17½@18c medium, 15@16c; poor, 13@14c. Ladles, extra, 14@14½c; medium, 13@ 13½c; poor, 12@12½c.

Cheese—Receipts for the week, 33,426 boxes. Exports for the week 10 203 boxes

The market has been steady with fair trading for both export and home trade accounts, and prices are closing firm at about last week's quotations. Cheese arrived in good condition and receipts of large sizes sold freely to exporters at 7¾@7⅞c. Small cheese were in larger supply but there was good trading and prices well maintained. Sales in Western New York Thursday were at 7¾@8⅛c. We quote: Full Cream, extra, 7¾@8c; medium 7@7½c; poor, 6@6½c.

Eggs - Receipts for the week, 70,741 cases. There is good quick demand for all strictly fresh laid eggs and market closes firm. We quote: N. Y. State & Pennsylvania 15@15½c per doz; Northern & Western, best marks, 14½@15c per doz: Other Sections 12½@14c.

177 Chambers St. DAVID W. LEWIS & CO.

CANTON, N. Y., June 12.—On the Board Saturday 2,145 boxes cheese were offered. They were sold at 7¾c. The offerings of butter were 1,400 packages. There were sales at 18c.

FULTON, N. Y., June 12.—To-day 22 factories were represented. There were 1,835 boxes of cheese. Large sold at 7⅛c; small sold at 7⅜c. There were 10 tubs of butter sold at 18c.

OGDENSBURG, N. Y., June 12.—On the Board Saturday, 1,445 boxes of cheese were offered. There were 102 boxes sold on the Board at 8 1 16c, and later the balance were sold on the street at 8c.

WATERTOWN, N. Y., June 12.—At the 5:30 close there were 14 lots aggregating 881 boxes of large white cheese purchased at 7⅛@7⅝c, an equal number going at either price. There were 23 lots of fancy large white cheese that were sold at 7¾c.

LITTLE FALLS, N. Y., June 12.—There were expectations of lower prices for cheese to day, so nobody is disappointed, unless it be that the decline is not greater. The transactions were 96 lots, 6,669 boxes at 7@7⅛c.

Butter—Sales of 28 packages dairy butter made at 15@17c; the ruling price being 16c.

UTICA, N. Y., June 12.—At the opening of the market to-day, there was indication of lower figures than those afterward realized. Features of the market were the disappearance of large white cheese, and a drop in the price of small cheese to about that for large colored. The sales aggregated 94 lots, 6,360 boxes at 7@7⅛c. The transactions on June 14, 1897 were 11,525 boxes, with 8c the ruling price. On June 13, 1898, were 7,530 boxes with 6⅞c as the ruling price.

The butter market continues firm. The sales on the Utica Board to-day were 22 packages at 17c; 90 at 18c and 30 at 18⅛c.

WASHINGTON, D. C., June 19.—Market steady; extras 19c; choice firsts 18c.

NEW ORLEANS, La., June 19.—Market quiet; creamery 19c; dairy 16c; ladles 13@14c.

NEWARK, N. J., June 19.—Market quiet 18½@18¾c for fancy creamery. Receipts liberal.

KANSAS CITY, Mo., June 19—Butter—Creamery, 16c; dairy, 13c.

Eggs—Fresh, 10½c.

CINCINNATI, O., June 19—Butter—Steady, 20c.

Eggs—Easy, 10c.

Cheese Steady; good to prime Ohio flat, 8@8½c.

PHILADELPHIA, Pa., June 19—Butter—Solid packed, separator creamery, extra, 18⅛@19c; creamery firsts, 18c; seconds, 16@17c Imitation creamery, extras, 16c; seconds, 13c. Ladle packed, extras 14c; firsts, 13½c; seconds, 13c Print butter, creamery extra, 19c; firsts, 18c; seconds, 16@17c.

Eggs—Pennsylvania and nearby 14½c; western 14¼@15c; southwestern, 14c; southern, 13½c.

ST. LOUIS, Mo., June 19—Butter—Weak; creamery, 15@19c; dairy, 12@15c.

Eggs—Firm, 10c.

Latest quotations for fancy creamery:—Buffalo 19c; St. Paul 17c: Minneapolis 16@17½c; Detroit 19c.

BALTIMORE, Md., June 19—Butter—Market firm; creamery separator extra, 20c; extra firsts, 18@19c; creamery firsts, 17@18c; creamery imitation extra, 15@16c; ladle extra, 14@15c; western store packed 11½@12½c.

Eggs—Market firmer; strictly fresh stock, 13½@14c.

BALTIMORE MARKET.

BALTIMORE, June 15—Butter—Considerable interest was displayed by both sides of the market at the opening, in the receipts of separator creamery, conditions being favorable to make of the situation either way; for the buyer, or for the seller; but the uncertainty was of short duration, for soon it became all to obvious that the buyers had enough at current prices, even before full distribution for consumption had taken place, and then, as in every other activity and enterprise there was "plenty of room at the top" for operators to indulge their appetites, if they had any. At the time of going to press, the edge seems to be off of the home demand, and unless something transpires by which the foreigners can be made an outlet for our surplus, it does not require a prophet to foretell the course of the stream of excessive supply that we natural'y expect to flow in at this season. The quality is not up to the expectations of most of the trade, and if a 95 point standard were strictly applied, very few lots would bring the price quoted for extras. Gathered cream goods are arriving in slightly increased quantity, and, being fairly attractive, find buyers numerous enough to absorb all offerings. The attention of the majority of the buyers being diverted from the top variety temporarily, is devoted to imitation creamery and ladle packed, and an increase business is reported in them. Receipts of store-packed continue rather light, with demand brisk; would advise liberal shipments.

Creamery Separator, extras, 19c; firsts, 18c; seconds, 17c. Gathered Cream, extras, 18c; firsts, 17c; seconds, 16c. Ohio, extras, 18c; firsts, 17c; seconds, 16c. Imitation, extras, 16c; firsts, 15c; seconds, 14c. Iowa & N. W. Ladle, extras, 14c; firsts, 13c; seconds, 12c. Ohio & Indiana Ladle, extras, 14c; firsts, 13c; seconds, 12c. Ohio storepacked, extras, 12c; firsts, 11½c. W. Va., extras, 12c; firsts, 11½c; seconds, 11c. Creamery block, (2 lbs.) extras, 21c; firsts, 20c; seconds, 19c. Creamery prints, (½ lb.) extras, 21c; firsts, 20c; seconds, 19c. Md. Va. & Penn. prints, extras, 19c; firsts, 18c; seconds, 17c.

Eggs—Receipts of choice, fresh stock is very light; there is quite a brisk demand for this kind. Heated or other faulty stock has to be sold on the open market for what they will bring. Market firm on all choice stock at 13c.

☞NOTICE—Ship your eggs in cases, and not in barrels or boxes; by so doing you will avoid their becoming heated in course of transit. Please bear this in mind.

Cheese—Arrivals are composed entirely of new cheese. The supply is quite sufficient for all demands; market quiet and irregular.

N Y. State Cheddars, fine, 8¾c; choice, 8½c; fair, 8@8¼c. Flats, fine, 8½@9c; choice, 8½c; fair, 8¼c. Small, fine, 8¾@9c; choice, 8½c; fair, 8¼c. Ohio Flats, fine, 8@8¼c; choice, 8c; fair 7¾c. Ohio Picnic, fine, 9c; choice, 8½c; fair, 8c. Swiss Cheese, fine, 13@13½c; choice, 11@12c; fair, 9½@10c. G. M. LAMB & BRO.

301 Exchange Place.

MANCHESTER BUTTER MARKET.

MANCHESTER, Eng., June 9.—Copenhagen reports the weather now perfect summer. Butter comes forward strongly grass flavored, although not always pure grass make. Everything pure and keeping is picked up at extra prices. There is no doubt that gradually as the quality of butter improves the market will firm up. Reports from your side are not altogether satisfactory, because butter, not pure grass complains of feeding taste. Quality and trade will all be better next week. Official Danish rate two kroner lower being within one shilling of the figures ruling for the ensuing six weeks of last year. So far the season has run very favorably, and the make hitherto backward now shows signs of increase. New York reports say, that in the states, "we are going through the same experience as usual at this season. Some receivers so fearful that they won't get enough of the fine make of grass butter that they are bidding and overbidding on about all the fancy marks of June and July make west, in entire ignorance whether the make is to be larger or smaller than the previous seasons. Naturally the make ought to be more, as the country is growing all the while. The same may be said of the consumptive wants; that is also increasing if we leave out of consideration the largely increased use of oleomargarine and process butter. Besides this we are having no export demand, nor are we likely to have for our fine butter at present prices."

Manchester had a fairly good market on Tuesday, though buyers were pressing for lower rates. Most fine quality well cleared—20,420 Danish and Swedish casks at sea for next markets or 267 more than last week with 2,197 Fins or 289 casks less—margarine steady. Arrivals of margarine via Hull 9,659 packages, via Grimsby 4,071.

DOWDALL BROS.

LIVERPOOL, June 19.—Butter—Good United States 62s.

Cheese—American finest white 42s 6d; colored 41s 6d.

COLD SKIMMING.

"Alpha" disc separators are the only separators capable of clean skimming at low temperature. This is physically impossible with any other machine, as every separator user knows who has ever tried it and properly uses an accurate skim-milk tester.

No separator user needs to have the manifold importance of cold skimming under various conditions explained to him. Many an "Alpha" machine has saved its cost in three months in this way alone.

"Alpha" separators are just as superior to other separators in a dozen other ways as in this one. The "discs" tell the story.

Send for descriptive and illustrative catalogues.

READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

Wanted—An honest and reliable man capable of managing a large dairy. Must be experienced in all dairy work and with all dairy machinery. Liberal wages to good man. G. C. STREET, Houston, Tex. 18-4

Scour Cure—Stops scours in calves. Large bottle $1.00. A. S. ALEXANDER, V. S., Evanston, Ill. 15-tf

Tamworths, ready to wean, $10 each, or $12.50 delivered. Hermanville Farm, P. E. I., Canada. 32-52

To avoid inbreeding I will sell my excellent herd bull, Linnie Graph, No. 4991 A. G. C. C. Dropped March 15, 1897. M. D. CUNNINGHAM, Kansasville, Wis. 19-2

Wanted—A good, experienced butter maker. Must thoroughly understand the making of butter and care of cream. G. E. BROWNBACK. Sinfield, Pa.

Outgrown our capacity—Will sell our Little Giant separator with 3 h.-p. boiler and engine, churn, butterwork etc., cheap, to make room for creamery machinery. G. S FOREST, Teeds, Iowa.

Wanted at once—A working foreman on dairy farm who is a good milker. Experienced and reliable. Single man perferred. Good dairy band is also wanted. Address A. D. BLAIR, Star Junction, Pa.

Wanted—Two first-class farm hands who can milk. A permanent job for one and perhaps both. Must be men of good habits. Address B. PARSONS, Havana, N. D. 19-2

Wanted—Position as buttermaker or dairyman. Good references. Two dairy schools. Can talk German. J. W. SCHIELD, Kinbrae, Minn.

Exceptionally Low Rates to Los Angeles, Cal., via the North-Western Line. Excursion tickets will be sold at greatly reduced rates from all stations, June 25 to July 8, inclusive, limited to September 4, 1899, inclusive, on account of Annual Meeting National Educational Association. Variable routes, delightful scenery. Side trips at low rates to points of interest Apply to agents Chicago & North-Western R'y 19-2

Very Low Rates to Milwaukee, via the North-Western Line. Excursion tickets will be sold from stations in Wisconsin, Illinois and Michigan at very low rates for the round trip, account of Milwaukee Carnival, to be held June 27-30. For dates of sale, limits of tickets, etc, apply to agents Chicago & North-Western Railway.

Exceptionally Low Rates to Denver, Col. via the North-Western Line Excursion tickets will be sold at greatly reduced rates from all stations, June 25 to July 11, inclusive, limited to October 31, 1899, inclusive. Variable routes, delightful scenery. Apply to agents Chicago & North-Western R'y. 19 3

Exceptionally Low Rates to Cincinnati, Ohio, via the North Western Line. Excursion tickets will be sold at greatly reduced rates from all stations, June 26, 27 and 28 (but not for trains arriving Chicago before June 27), limited to July 5, 1899, inclusive, on account of National Sangerfest. Apply to agents Chicago & North-Western Railway. 19-2

Fourth of July Rates.—On July 1, 2, 3, and 4 the North-Western Line will sell excursion tickets at low rates to points on the North-Western System within 200 miles of selling station, good returning until July 5, inclusive. Apply to agents Chicago & North-Western Railway. 19-2

Exceptionally Low Rates to Detroit, Mich.,—Via the North-Western Line. Excursion tickets will be sold at greatly reduced rates from all stations. July 3 to 5, inclusive, limited to August 15, 1899, inclusive, on account of Annual Christian Endeavor Convention. Apply to agents Chicago & North-Western R'y. 19-2

An Interesting Address on Cattle.

Prof. Eugene Davenport, Dean of the University of Illinois, gave a very instructive address before the Illinois Live Stock Breeders' Association, at Springfield, Ill., recently, his topic being, "An Undeveloped Market for Pure Bred Males."

We can only summarize the principal points made in the address, which were in brief, as follows:

"For more than a hundred years, and especially in the last half century, favorite blood lines have been preserved and protected from contamination. More than fifty breeds of live stock are owned and bred in the United States, each protected by an association that believes in its merits, and by a system of records that insures purity of blood.

Less than one per cent of all the cattle of the United States are registered animals of any breed, and only sixteen per cent are grades of one-half blood or better. Most of the other 84 per cent have doubtless enjoyed some advantage from the general diffusion of blood.

The great mass of farmers breed cattle in a blind effort to secure something to eat up their grain and roughage. The 84 per cent cannot bring their owners anywhere near the profit that the 16 per cent does, but the average farmer does not know it. The breeder knows these things; the farmer is a grain raiser and knows but little about it. He may never become a breeder, but for his own sake and profit, he ought to become a good stock raiser, with an accurate eye for selecting the right kind of cattle for his purpose. The half million registered cattle are abundantly able to produce pure bred sires and give every calf one good parent.

In the north central States 1.21 per cent are registered cattle, and 22.21 per cent are grades; while in the south central States their numbers are .46 of one per cent and 6.77 per cent, respectively. Iowa leads the states with 60,000 registered cattle, and though the per cent is lower than in Illinois, (1.2 against 1.4), she has made better use of them and has 30 per cent of grades against our 21 per cent. The dairy reports show that the largest returns per cow are invariably in those states that have the highest per cent of registered animals and their grades. From any point of view the cattle industry is prosperous in just about the proportion that the blood of the improved breeds have been diffused among the masses. But the diffusion is surprisingly small and eminently unsatisfactory, both from the interests of live stock in general, and from that of the professional breeder.

DAIRYMEN INCONSISTENT.

The dairymen are the worst sinners in this matter of neglect, and they ought to be converted with a strong hand and a stretched out arm. As a class of stockmen, they expect to buy a cow fresh, keep her till dry, then sell her for beef and buy another. Their argument is that in this way they never get any old stock on hand. This is like selling an engine for scrap iron after the first year's run to prevent its getting old. These dairymen are too anxious for milk to spare a little to raise a calf, besides they do not like the trouble.

Here is a barn full of cows (presumably good ones) kept constantly for their milk. What a place to do breeding with almost no expense! If a cow is worthy to occupy a stall and consume good feed, if she can provide a profitable market for the products of the soil, then she should produce regularly, by a sire of the best breeding, in order that she may leave worthy successors behind her. Any dairyman can raise a better cow than he can buy, and for less money. His business naturally affords him all the materials, save only one animal to head the herd, and you who breed good cattle must convert this erring brother to rational methods."

In the great dairy districts, like that of Elgin, there are but few, comparatively speaking, well balanced dairy farmers, who comprehend the finer economics of breeding and handling, even grade dairy cattle. The farmers there raise but few calves; indeed, less calves are raised in proportion to cows kept, than in the districts where few cows are kept. These farmers pay excessive prices for big, beefy cows, generally of low dairy capacity, and performance, and so throw away good money in that way that had better be spent in raising good cows.—ED. DAIRYMAN.]

"Grading is the easiest possible breeding, and therefore fitted for the man who is not, either by nature or by business relations, a breeder. You who breed registered stock are attempting to improve their character with successive generations by the principle of selecting, operating in favor of desired variations. I hear breeders talk a great deal about heredity, but variation is the principle out of which improvement comes. It is your business to catch these valuable variations and fix them in individual animals that they may be sent out as sires, to secure to the live stock of the country by heredity what you have fixed in your herds, by variation and selection. It is your function to originate and fix quality and sell it to the general stock raiser. It is his function to use it. Grading provides the legitimate market for the qualities you have produced and it is the only way in which they can reach the stock raiser. To advocate grading is not at all to advocate mixed breeding. Grading is not a temporary, but a permanent policy for the general stock raiser.

SIRES CHEAPER THAN DAMS.

On the average $2 is sufficient to provide a calf with a registered sire from some of the great recognized breeds. Whatever the figure may be it is comparatively slight. But the expense to provide a calf with a pure bred dam will not be less than $20 and probably more. Any man who soberly considers this for a moment will see that it is entirely feasible to produce commercial stock with the best sires, but not with the best dams; their numbers are too few and their produce is too limited. As it is, less than one out of six calves enjoy the advantage of good parentage on either side.

Breeders have been at fault in advocating too high methods, standards and painstaking care for grades. Better let the cattle educate the farmer, but get him started as soon as possible to grade up.

MUST STIMULATE DEMAND.

The demand for pure bred sires will never come of itself. It must be stimulated by men who are themselves personally and directly interested in its development. Education is always from above downwards. Breeders cannot go on practically confining their sales to their own numbers. They must place their animals in the fields of the farmers of this country and think more about developing the market for a bull at $100 than in trying to sell a cow for $1,000 to some novice who has more money than brains. Let us get together, we who breed and we who grade, and buy and sell and get gain."

The South Dakota State Fair.

ED. HOARD'S DAIRYMAN:—The undersigned has been chosen Superintendent of the Dairy Department of the South Dakota State Fair, to be held at Yankton, September 25 to 29, 1899. It is the desire of the Board that this department be one of the leading features of the fair, and no time or labor will be spared to make it such.

Last year the dairy building was enlarged and a commodious ice box put in, so that there is ample space to exhibit machinery and room for all the butter that will be sent. The Board will do all in its power to make this department a success, but it needs the aid of friends of the dairy industry outside the state to make it what it should be.

Will you not aid us? We want exhibits of machinery and supplies, we want offers of special premiums, and we want a large attendance of outside friends.

All special premiums will be advertised in the premium list if we are notified at once.

E. M. BENNETT, Supt.

Clark, S. D.

Seasonable Notes From Michigan.

Ripening Cream.—Packing Butter.—Private Customers for Butter.

ED. HOARD'S DAIRYMAN:—Noticing in an issue of your paper that a subscriber is having trouble with his butter, I offer a few suggestions. The complaint is that the butter is strong, and a remedy as well as a reason for this is requested.

On the average farm the amount of butter made during winter is not great, and there is apt to be too long a period between churnings. This more than any other thing causes the off flavor which much of the winter butter possesses. The cream is held too many days awaiting a time when a sufficient amount shall have accumulated to make a churning. Cream becomes bitter when allowed to stand too long, and this often occurs in cold weather, before souring takes place. The churning should be done at least twice a week, the same as in summer. Where milk is set in pans in the pantry, it is sometimes left standing several days before skimming, and it frequently occurs that it becomes bitter before the cream is removed.

I have actually known milk to stand in this way until specks of mold appeared upon the surface of the cream. Then when skimmed the cream was kept several days, or, perhaps, a whole week longer before churning. It is needless to say butter made under such circumstances will be strong from the very first.

With such conveniences as the average housewife has at hand for ripening cream, it is quite difficult to get it done properly either winter or summer. In winter it must be warmed, and in summer cooled artificially, to produce the desired result.

My experience has been that winter cream held at 40° cannot be properly ripened in 24 hours merely by bringing it into a room where the temperature is 60°. It must be warmed to somewhat above that point and then not allowed to drop below it. It facilitates the ripening process if a starter in the shape of a pint of buttermilk saved from the last churning is added to it at the time of warming.

Cream should be stirred at intervals during the 24 hours preceding churning, as evenness of temperature is difficult to maintain, but by stirring, thus bringing fresh cream to the sides of the can or jar, a more equal degree of warmth is secured.

One creamery in this county, is now pasteurizing in a crude way all the cream, before making into butter. It is placed in the vat and heated to 155° then allowed to cool down to churning temperature. This is done as soon as possible after separating. The butter is said to be of superior quality when made in this manner. All trace of bad flavor disappears from cream so heated.

We are pleased to see an increasing interest among farmers and small dairymen in regard to finding special customers for their butter. It pays to do so. While the regular dairyman may be able to find a commission merchant who will deal honestly and satisfactorily, this is not always the case with the one who has but small shipments to make.

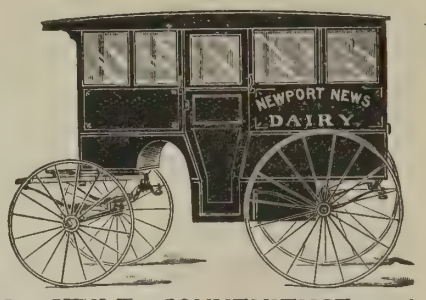
After deducting freight, cartage, and commission, there is often not much left, and the butter might better have gone to the local grocer so far as profit is concerned. This is an experience which most dairymen have had at some period of their business operations. Butter needs to sell at considerably more than local prices in order to pay for shipping.

It is frequently the case that returns are accompanied by a statement that the market was a little off when the butter arrived, which is supposed to account for shortage in remittance.

Then, too, the small number of cows kept often renders it impracticable to ship butter to a commission merchant. It needs to go in considerable quantities, thereby proportionately reducing freight rates and cartage. Where but half a dozen cows are kept, and these not all in full flow of milk at one time, it will not be wise to pack in large firkins, the most common method of shipping.

Butter will not sell at top prices if there is a difference of quality or color between the bottom layer and the top one. One needs at least sufficient cows to fill a tub each week, and few farmers can do this for more than a short period each year. Taking these things into consideration, I advise against the sending of butter to a commission man, and advocate private customers. These may be obtained in one's home town or in a distant city, whichever is preferred. There is no difficulty in securing customers if the butter is satisfactory, nor is there any danger of losing them when secured, if it remains so. There is no profit to go to the middle man, but all goes into the pocket of the producer. A hint right here to those who pack butter in crocks or tubs for family use. Pack the butter in layers three or four inches deep, and cover each layer with a circle of butter cloth. This facilitates the cutting out process when it arrives at its destination, as the butter can be removed in neat slices for the table, an entire layer being taken out before the next lower one is disturbed. It also saves crumbling, and the messy appearance which a crock of butter sometimes presents when in process of use, if packed in the usual manner, and a piece *gouged* out shallow in one place and deeper in another. W. C. ROCKWOOD.

Mich.

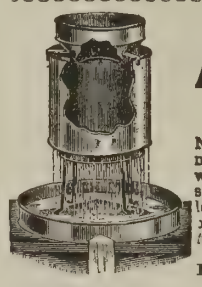


Fancy Cheese.

In Europe the dairymen make a large number of small fancy cheese, which have a wide market, and many of which are imported into this country in comparatively large amounts. Following is a description of a few of the most noted:

Camembert.—A French cheese made from whole or partially skimmed milk. It is very fine and delicate in flavor when well made, and greatly in demand at all seasons. The flavor depends on the successful growth on the outside of the cheese of a fine mold—which is first white and then blue—the mycelium of which penetrates into the interior of the cheese, and causes a change in its body equivalent to ripening. It is ripe in about four weeks.

Coulommiers.—A whole milk cheese sold fresh, or at least within ten days of manufacture. It sells readily during the summer months, and will return about one shilling per gallon for the milk used. Coagulation is protracted, and ripening really takes



The World Cannot Show Its Equal

In STYLE, CONVENIENCE and DURABILITY.

Body hangs but 17 inches from ground, and turns can be made in its own length. Sold direct to Dairymen at bed rock prices. For description and price address,

THE NATIONAL WAGON CO.,
Chillicothe, Ohio.

The YOUNG AERATOR And Cooler

Needs no water or ice, removes all odors and gases, warranted to keep milk sweet from 6 to 12 hours longer than any machine on the market or money refunded. Circulars free,

W. H. YOUNG,
Box 135, Aurora, Ill.

GALVANIZED STEEL TANKS — MADE BY C. E. BANTA MFG. CO. CHICAGO — GUARANTEED NOT TO BURST

QUALITY COUNTS.

If you are interested in a **Tank** of any size, shape or capacity, write to-day for our free Catalogue. WE HAVE NO AGENTS, but sell you direct from our factory at lowest wholesale prices. **C. E. BANTA MFG. CO.,** Dept. 32 A, **Chicago, Ill.**

The DROWN PATENT COW STALL guarantees perfect comfort to the cow and cleanliness of milk. This gives greatest economy of food. No TIES. It costs more to not have than to have it. Send for information to H. C. DRAKE or M. J. DROWN, Madison, Wis., for Wisconsin; other states, M. J. DROWN.

Mention HOARD'S DAIRYMAN when writing.

place before the curd is ladled out into the forms.

Port du Salut.—A semi-hard cheese, subjected to slight pressure. It is very easily made, and ripens in about six weeks. It resembles a Gruyere in taste, but is milder.

Pont l'Eveque.—Is somewhat similar to the last, but is smaller, and square in shape. The body of this cheese, when ripe, is soft and yielding, and the ripening is brought about by aerobic ferments.

Gorgonzola.—Is made of two curds from rather poor milk. No pressure is applied, and it ripens in about eight weeks. The interior of this cheese grows a green mold—*benicillium glaucum*—and it is skewered to forward its growth. It is cured in a draughty cellar. The best cheese grow a peculiar red fungus on the outside, and to imitate this many Gorgonzolas are colored with brick dust and flour.

CREAM AND MILK CHEESE.

Gervais.—This is made from a mixture of two-thirds milk and one-third cream. Three quarts of the mixture make one dozen cheese. This is set at a low temperature, and the coagulation takes forty-eight hours. It requires about three days to make, and is sold when quite fresh. They are generally sold retail at 3d each.

CREAM CHEESE.

A good cream cheese is made from the best quality of cream—8 lbs. of cream will make 6 lbs. of cheese. Each cheese weighs about 4 ozs. and is generally sold at 6d.

Beans As Stock Food.

Prof W. A. Henry recently received the following letter from a Waupaca county farmer:

"I have read your annual reports and bulletins of the experiment station, also farmers' institute bulletins but do not find anything in regard to beans as food for stock. I have raised a great many and feed them and am satisfied they have used me well. I had about 20 acres last season. I should like to have your opinion of beans as a feed for stock, and what you consider them worth per bushel, when timothy hay is worth $9 per ton, corn in ear, 50 cents per 100, oats 27 cents per bushel. I have been grinding and feeding to work horses, also to my breeding mares, to the sheep and milch cows with, what I consider, good results. I have also fed whole to sheep. I wish you would give what information you can in regard to beans as a feed for different farm stock, including milch cows; also do you consider it safe to feed to breeding ewes and breeding mares at this season of year? In feeding to sheep would you feed whole or ground?

"Please state the percentage of the different food elements, protein, carbohydrates, etc., also please state how much you would consider should be fed per day, in pounds, to different kinds of stock under different conditions.

"Perhaps you have a bulletin that covers this ground; if so please send it or tell me where I can get one. I have about 250 bushels of beans at present—some old."

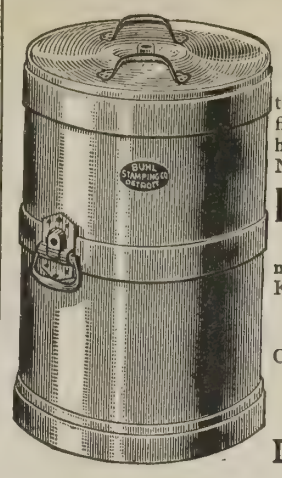
Prof. Henry's reply to the above inquiries will prove of interest to many. It was as follows:

"Our correspondent brings up a subject of much interest, though unfortunately one about which we cannot give as much information is is desirable. Beans are not used to any extent for stock food in this country because of their worth and high market value for human food. In the bean districts, however, the buyers in handling the crop sort the beans carefully throwing out any which are dulled in color or injured in quality through rains, mildewing, etc,. at harvest time. Farmers can often buy these cull beans at a low price, and those who have done so find them valuable for feeding stock. Of course good bright beans would be somewhat more valuable than those more or less injured.

"The writer is unable to find the results of any digestion trials with beans as a feed for stock. We may however, compare the table bean of this country with peas and also the horse bean of Great Britain. In England the farmers grow a large coarse bean known as the "horse bean", which is valued highly as a strong feed for work horses. In the table given below I have added oats and bran to the list for comparative purposes.

Tabel showing digestible nutrients in 100 pounds of various farm feeds:

	Protein Lbs.	*Carbohydrates Lbs.*	*Ether Extract Lbs.*
Peas	16.8	51.8	.7
Horse bean	22.4	49.3	1.2
Wheat bran	12.2	39.2	2.7
Oats	9.2	47.3	4.2



"The common bean which probably comes between peas and the horse bean in nutrients is evidently richer in protein than either bran or oats. Protein is the constituent of feeding stuffs which goes to build up the muscles of animals and may be used for heat, energy or fat production. In carbohydrates beans are fully as rich as oats. The carbohydrates furnish heat and energy and are the main source of fat with farm animals. Beans are not rich in fat or ether extract. Corn, our most common feeding stuff, is poor in protein. Beans are therefore a complimentary feeding stuff and should be fed with corn when possible. Young animals, cows giving milk and hard worked horses require more protein food than do fattening animals, which make their most economical gains where a large supply of carbohydrates is provided. For certain uses in feeding, as indicated above, I should value good beans as worth 25 per cent more than the same weight of oats or wheat bran.—W. A. HENRY, *in Wisconsin Farmer.*

He Is Surprised.

Says a writer in *Stock Breeder*:

"I believe that it can be easily proven that there is more room for improvement in our dairy herds and their management than there is in any other line in the whole field of agriculture. When we stop to think that the average make of butter per cow in the United States, as reported by the last census, was 130 pounds per year, we are surprised. When we put this fact by the side of the thoroughly practical one, that it is possible to have our dairies produce an average of 300 pounds, we are still more surprised. There are many dairies in the Uuited States that produce more than 300 pounds of butter annually per cow. There is not the least doubt of the practicability of securing dairies that will do this grade of work. There are plenty of cows scattered all over the United States that will do this quality of work when intelligently handled.

The DAIRYMAN is surprised at one thing more: That there is such a host of men keeping cows that take no pains whatever to know the truth concerning their herds. Did they do so, *they* might be surprised.

The Best Factory Cans.

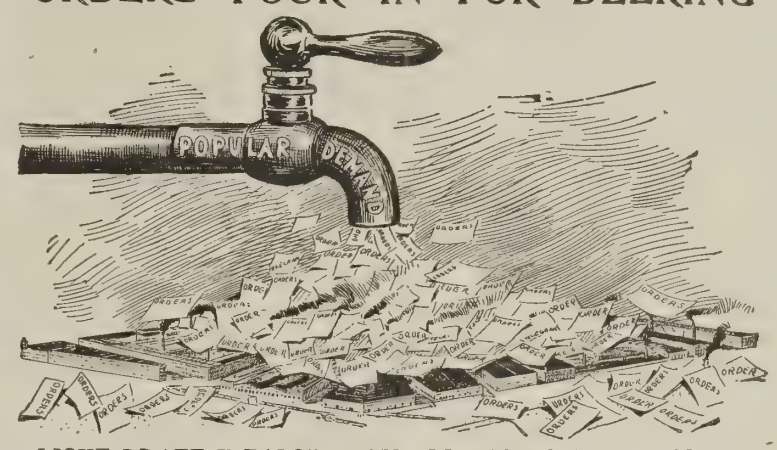
The strong points of the Buhl Factory Cans are their great strength, heavy coating of pure tin, and fine finish. They do not rust like common cans, have no crevices inside, will not leak, and need no repairs. No other cans have the Genuine Heisey Side Handles.

Look for the Milk Can Trademark.

This Can has 3 welded, tinned, wrought-iron hoops, tinned malleable side handles, and heavy XXXX genuine Cookley K cylinders.

Capacity 15, 20, 30, 40 and 50 gallons.

Refuse imitations. We make all patterns and sizes of Milk Cans, and will gladly mail you our hand-book free.



We Make Prompt Shipment.

Mention HOARD'S DAIRYMAN.

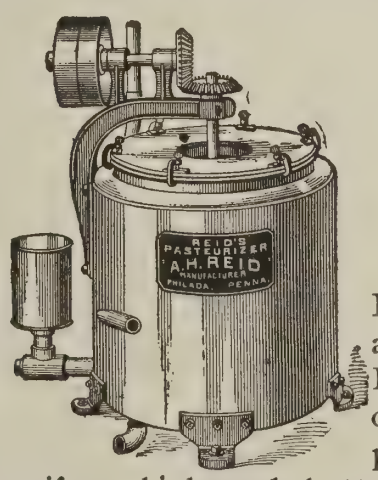
ORDERS POUR IN FOR DEERING

"LIGHT DRAFT IDEALS" FROM ALL POINTS OF THE GLOBE.

The largest single factory of any kind in America is running day and night to supply the demand.

There is no important grain-growing country in the world where **Deering Harvesting Machines** are not in use.

The machines that have a reputation for steady, reliable work, light draft and great durability are everywhere sought after.



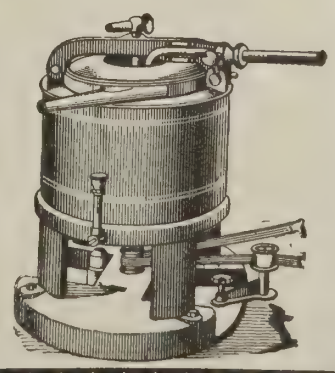
Deering pioneered and popularized roller and ball bearings in binders and mowers.

Deering machines are built to meet the practical needs of the harvest.

They are the kind that don't get out of order. They are easy on horseflesh.

That's why the nations of the earth unite in endorsing **Deering machines.**

DEERING HARVESTER CO., - Chicago, U. S. A.



You Can't Deny A Fact.

Practical and personal experience with the Reid Pasteurizer is the best test of the merits of pasteurization and the strongest argument in its favor. The Reid Pasteurizer is a fact which upsets the theories of the opponents of hot skimming. The creameries that use it produce perfect cream for all purposes and make the most uniform, high-grade butter, entirely and always free from bad flavor, and undesirable odors. A fair trial of the

REID Pasteurizer

is more convincing than any amount of talk. Write at once for complete description and price and don't forget to ask for the **Reid Long Spindle Separator** book. All free by mail.

The Conformation of the Dairy Cow.

[Address delivered before the Rural Science Club, of the University of Tennessee, May 29, '99, by Professor ANDREW M. SOULE.]

I have been in somewhat of a quandary as to the subject to choose for discussion, this afternoon. I thought, perhaps, the subject of the conformation of the dairy cow would interest you, because it is, undoubtedly, an important subject, and one that you can well afford to study intimately. Probably one reason for my choosing this subject is because this is a phase of instruction which we propose, especially, to emphasize here in our agricultural course. In this respect, we are to be congratulated, as our position is such as to place the use of many magnificent herds, besides our own, at our disposal for this work. It does not take a great deal of equipment to develop the subject of stock judging, and yet special training along this line, is highly important to every agricultural student. It is a subject that will be of interest to you in any calling in life. For example, if you go over the city of Knoxville, you will find a great many men who keep cows, and the question that will be asked by nearly everyone is: "How shall I know a good cow when I see her?"

Now, in college work, where you take a regular agricultural course, we commence with the score card. On each card we note, systematically, the characteristics of several individuals, until we become thoroughly familiar with the location, shape and form sought in the respective points of the dairy animal's anatomy.

After you have passed the "embryonic" stage of the score card, you come to the stage of "expert judging," where you will have, probably, half a dozen cows, from which to pick out the best. You should now be able to state your reasons for selecting a particular cow, and what are the superior points of one and the defects of another. In other words, train your eye, so that, if necessary, you can make a judgment in two or three minutes. I do not mean to say that you can, in every instance, pick out the best cow from a herd. That requires a great deal of study and practice. But you can become so expert that you can, very often, find the best cow. You can generally pick out a good cow, and tell those that are indifferent.

First of all, we must consider the cow as a machine for the economic production of milk and butter. And she varies for those two purposes. If you find a cow that gives 5,000 pounds of milk and yields 300 pounds of butter, you have a cow well adapted for that specialty. On the other hand, if she gives 8,000 pounds of milk, making 200 pounds of butter, she will prove more remunerative for the first consideration.

Commencing with the head, we have the poll, the eye, and the dish, three points that should receive special attention in a dairy cow. Our arguments, with regard to these points, are based on observation,—not on my own personal observation alone, but on the observation of those who have had wide experience; and we find, for example, that a cow that has the poll, or the point between the horns, wide, is generally a good milker. Now, we assign as a reason for this the fact that it is an indication of nervous energy. When you see a man of high, broad forehead you expect him to be a brainy man. We desire and seek the same thing in a cow, for the reason that milk is the direct product of nervous energy. We want every point that indicates high nervous energy strongly developed. And a very large brain indicates a well-nourished nervous system.

Next look at the eye. Probably the eye is one of the best indicators of nervous energy, or character that you can find anywhere. When you meet a man whom you do not like, you condemn him probably as much for his eye, as any other feature of his face. The eye seems to show the soul. The same thing is displayed in the cow. We look for those things that indicate good temper, or, we might say, for pleasing features. We look for those features that are attractive. You will find the eye of the Jersey cow probably the most highly cultured eye in the dairy world. A large, limpid, clear, placid eye, it gives you the idea at once of a gentle, kindly disposition, and at the same time of a strong, vigorous nervous temperament.

Following the eye comes the dish of the face. The dish is not due so much to the curvature of the nasal bone as to the prominence of the eye and brain. We count the dish a good point for that reason.

The next point to consider is the neck. Now, the neck of a good dairy cow will be longer than that of a beef animal. In the dairy cow you want a rather loose-jointed animal, with a long neck and a loosely wedge-shaped body. In the steer you look for a short body, and a compact, thick neck. For two reasons we do not want that type in the dairy cow. Where you find a heavy, short, thick neck, you have, as a rule, a tendency to meat production. Whereas the opposite tendency would naturally be sought. Second. Animals require a certain quantity of food for maintenance; all over that, produces milk, fat, or energy, as the case may be. In a dairy animal that has both tendencies, instead of all the surplus food material going to the production of milk, it is divided between two antagonizing purposes, and you get a meagre flow of milk of variable quality. Therefore we look for the neck to be rather long, and thin from side to side, or ewe-necked, as it is sometimes called. It should also have depth, and be free from loose flesh, or dewlap.

If you have the dairy cow as she ought to be, you will find her narrow at the withers. The beef animal should be broad there. In the chest region, however, there must be lots of room for the lungs, liver, and other excretory organs of the body. This is the center of oxidation. The lungs perform this most important function. Upon their ability to purify large quantities of blood will depend in large measure the milk flow, and of course, also, the health of the animal. We cannot get the lungs too large and strong, or the animal too broad through the thoracic cavity. If you find an animal that is narrow and cramped in the chest, do not buy that cow; she may be troubled with tuberculosis. In the chest, endeavor to secure great depth. That is an indication of the vitality of the animal.

We have in the cow the quadruple wedge-shaped formations. Strictly speaking, there are more than four wedges, but this is the number commonly considered as important. One is from the withers downward, increasing in width, known as the anterior wedge. Then we have the posterior wedge, of great width at the pelvis and decreasing toward the ground. Next follow the superior and inferior body wedges, increasing in width toward the posterior portion of the body. The definition of these wedges should be carefully scrutinized and emphasized.

The body, or barrel, of the cow should be very large, for the reason that her digestive and assimilative power is the direct measure of her productive capacity. Hence, that portion of the body containing the digestive and secretory organs should be tremendously large, wide and deep to give play to their respective functions. In general, then, the outline of the dairy cow, as viewed from the side, would be as follows: First, the neck is narrow and long, the shoulder point is rather prominent, the belly deep, broad and expansive, the flanks somewhat contracted, the hooks wide apart, and the rumps broad. In a beef animal you will find that from the shoulder to the rumps is almost a straight line when viewed from the side.

A very important point is the milk veins found along the belly of the cow. They should be very tortuous. They wind about on the belly and pass into the body, through orifices in the rear of the fore flank. Their duty is to convey the veinous blood to the lungs for purification. Hence, the larger the vein and the greater its ramifications the better indication it is that the circulation of the blood through the udder is very large; and naturally the larger the circulation of blood the greater will be the milk production; because milk, after all, is really a product of the blood.

To sum up, then, the strongest indication of a good dairy cow, as shown by the form, would be about as follows: First of all look for the wedges. By a good dairy cow I do not mean that she must be skin and bones merely. I do not believe that a cow can reach perfection for dairy purposes and be an emaciated skeleton, and yet she should not be rolling in fat, as some of the beef types are. I believe that a cow has a maximum capacity for milk and butter production. You can feed a cow so much and she will use that for her own maintenance. Feed her more and you will force her up to her individual capacity, but she will be just as good a dairy cow. A cow need not be skin and bone. If you keep her in that condition you will generally give her tuberculosis. I would look for a wedge shape neck, a clear eye, and a high forehead. Examine the breadth of the hooks and rumps, examine the form and texture of the udder, and notice minutely the development of the milk veins. That portion of the udder where the little white hairs cover it is spoken of as the milk mirrow; and when it is large and well developed that is an excellent indication of good dairy production. I would never buy a cow without testing her by the scales and the Babcock method for butter fat. I would also want to know her pedigree, who and what her father and mother were, and two or three dams back. Some udders are a delusion and a snare. When the udder stands out after milking, or is "beefy", you will find as a rule a cow of limited productive capacity; whereas, if the udder collapses and folds on itself at the posterior suture, it is an excellent sign.

These are just a very few points which may serve to give you some idea of the significance of the conformation of the dairy cow.

CHARTER OAK HERD, JERSEYS. Stock Young and Old, Either Sex of excellent breeding for sale. J. P BRADBURY, Pomeroy, O.

Hood Farm Jerseys Combination, Eurotas and St. Lambert Blood combined in One Bull. Seldom at this day can you get this great blood so close up Bull dropped Oct. 20, 1898, Solid Color. Sire, Brown Bessie's son, 50 per cent. Combination. Dam, Bombazette, by Prince Pegis, that sold for $ 2,500 at auction, a son of Mary Ann of St. Lambert, 36 lbs. 12¼ oz Write for price. HOOD FARM, Lowell, Mass.

Introduce Milking Jersey Stock INTO YOUR HERD. by buying one of our bull calves. Our herd of 325 has been bred for milk for 17 years. Best blood, size and constitution. Selected stock. Large English Berkshires, all ages, at their best. Write for our "little book", FILSTON FARM, Glencoe, Md.

High-Class JERSEYS The blood of Combination. (Sire of 25 in list) through Brown Bessie' (Champion Butter Cow at World's Fair), and Diploma 16219 sire of 48 in list including Merry Maiden Young Bulls, also cows and heifers bred to Recorder 29239–son of Brown Bessie. Printed pedigrees. State what is wanted. H. C. TAYLOR, Orfordville, Wis.

We Have Sold SEVERAL OF The A. J. C. C. COWS advertised March 17th (see page 92), in fact, we quoted prices that made them desirable. There still remain some as well bred as those sold, which we think genuine bargains. We also have a few heifers that will be right to breed at time of turning out to grass. For cows, write for List No. 3, giving short pedigrees; for heifers, List No. 2. WINTERGREEN HILL FARM CO., Scottsville, N. Y.

For Sale . . . BULL CALF, Grand-son of the great Exile of St. Lambert 13657, sire of 72 tested daughters, "more than any other bull, living or dead." He is thrifty and good size; solid fawn color. His dam has a butter test of 15 lbs. 8½ oz., in seven days. He will be sold cheap. P. J. COGSWELL, Rochester, N. Y.

BILTMORE FARMS' JERSEYS. This is a working Herd of 250 of the best Native and Imported breeding, selected for work at the pail, constitution and individuality. All Tuberculin Tested. Above the fever line, so we can ship anywhere. Some Choicely Bred BULL CALVES out of great cows and by the best sires for sale at Dairymen's Prices. Also large English Berkshires, imported and native bred. Apply to GEO. F. WESTON, Supt., Biltmore, N. C.

MILLER & SIBLEY'S JERSEYS. Ida's Rioter of St. L. leads all other bulls in average for 29 tested daughters, viz: over 20 lbs of butter apiece in a week. All full weekly tests, by eight different owners. He weighed 1,760 lbs. His dam's record, 455⅓ lbs. milk, 30 lbs. 2⅓ oz. butter (official test) in 7 days. FOR SALE—Grandsons and granddaughters of Ida's Rioter of St. L.; also cows in calf to his sons. 224 First Prizes and Sweepstakes at 22 State Fairs or great Expositions. Big cows, Sound cows, Heavy Milkers and Great Butter Makers. Our Adelaide of St. Lambert gave 82¾ lbs. milk in one day, 2005¼ lbs. in one month, the world's Jersey record. Many other championship records. No catalogue. Special literature sent if this paper is mentioned. No animal sold for less than $100. Lowest price for quality. Every animal tuberculin tested before sale, if desired. Also for sale Children's Ponies and Imported Shropshire Sheep. Franklin, Venango Co., Pa.

The Lone Tree Jerseys. THE largest collection of high testing cattle in the West, including home-bred and Island cows. Show and breeding stock always in supply. Especial attention given to furnishing foundation stock for pedigreed herds. A superb lot of young bulls and heifers now in special offer, including some sure prize winners. Introduce Fresh Island Blood Into Your Herd. SIRES IN SERVICE:—The prize winning IDA'S RIOTER OF ST. LAMBERT 10th, the champion CATONO KHEDIVE, the champion CZAR COOMASSIE, and IMP. GOLDEN BAR, inbred through his sire, Aristocrat, and his dam, Imp. Sandgate, to Golden Lad, the greatest bull on the Island of Jersey. Write for what you want. Visitors always welcome. JOHN E. ROBBINS, Greensburg, Ind.

Pure Bred Tamworth Pigs, Bacon curers choice. Pure Bred Ayrshire Cattle, largest imported herd in America. Stock all ages for sale. R. G. STRAOY, Box 720 Brockville, Ont., Canada.

St. Lambert Jerseys, all ages, both sexes. Some from tested cows at low prices. W. J. HUSSEY, Mt. Pleasant, Ohio.

THE Evergreen Farm Herd of A. J. C. C. Jerseys is now headed by St. Lambert of Brodhead, whose pedigree is unequaled in the northwest We should be pleased to have anyone in want of Jerseys to write us for catalogue, stating just what is wanted. N. N. PALMER & SON, Brodhead, Wis

FOR SALE "Reta's Parole," 20 months' old, solid color, and standard bred. Fine individual and well behaved. Direct blood of best St. Lamberts and Combination. F. L. GASTON, Normal, Ill.

ST. OMER HERD Choice lot of Exile and Signal bulls now ready for service. All stock tuberculin tested. JOS. T. HOOPES, Bynum, Md.

GREEN PLAIN HERD POLLED JERSEY CATTLE Recorded stock FOR SALE. Inquries promptly answered. W. H. FORBES, Clifton, Ohio.

Diplomas Combination 39962. For sale—Bulls and Heifers by him out of Fancy's Harry. Signal cows some of them tested. Write to J. E. TYRRELL, Marysville, O.

ONE YEARLING BULL Out of a tested dam and TWO BULL CALVES out of large milking dams, for sale. Write for price. W. R. THOMAS, Bellmore, Ind.

PROSPECT HILL JERSEY HERD. WISCONSIN PRIZE HERD. Young Stock from 400 Pound Cows for sale. Come and see them. TUBERCULIN TESTED. F. H. SCRIBNER, Rosendale, Wis.

Linden Lawn Farming Co., OLNEY, ILL. Estab. '90. (*Capital Stock $100,000.00.*) Inc. '97. 640 ACRES. Breeders of Jersey and Aberdeen Angus Cattle. Poland-China and Yorkshire Hogs, Pure bred Poultry. Send for our plan of Co-operative Farming and Investments. C. S. MACK, Manager

Service Bull, Pedro's Handsome Prince, No. 42794. The cows in this herd are of the best families of milk and butter producers. We have for sale young bulls by Pedro's Handsome Prince and Exile of St. Lambert 55, No. 36073, out of tested cows. Write for prices and pedigrees.

The Stack Silo.

ED. HOARD'S DAIRYMAN:—Replying to your Jamaica correspondent in this weeks' DAIRYMAN, relative to stack silos, permit me to say Blunt's Patent Screw and Lever Ensilage Press is made by the Ensilage Press Co., Ltd., Leicester England. T. W. Lawford, Cedar Croft, Lawford Co., Va., some years ago advertised that he had the sole agency for the United States and Canada. So far as known, however, no stack silos have been built in this country.

I am not sufficiently acquainted with the conditions in Jamaica to say whether a stack silo system would be apt to give satisfactory results there, but I doubt it very much. In England and other European countries where stack silage has been made in the past, they are now abandoning the system, going over to our American system of round silos, if the information which I have received is correct. This is not to be wondered at, as nobody would be apt to enjoy, for any length of time, the work of hauling to the manure pile, half or more of the fodder they put into the stack.

My advice to the Jamaica gentleman would be that he build a small tank silo. If he does build such a silo, he should build it well and should use bevelled staves, so that there would be no chance for air to get in and cause the silage next to the wall to spoil. F. W. WOLL.

Wisconsin Experiment Station.

Ensilage for Fall Feeding.

We have concluded that the simplest and most economical way to provide both summer and winter feed for our dairy cows is to store enough silage to supply them for ten months, and to this end we will plant about 50 per cent more fodder corn than has been our custom heretofore. The pasture at the state farm was never better than it is this year. We turned out the cows on the first day of May, and notwithstanding the fact that the grass is luxuriant, when the cows come to the barn in the evening they take a good mess of ensilage with a relish. Before the cows are brought up some ensilage and a little meal is put in the mangers, and we notice that if the meal is not thrown on the ensilage they will eat the ensilage first. An acre will produce from 12 to 15 tons of ensilage, and a cow will take from 20 to 40 pounds per day, according to the condition of the pasture; so it will not be difficult to estimate the amount of corn that should be planted broadcast or in drills.

This year we will turn under 10 acres of either pasture or meadow and sow to fodder corn. In the fall it will be put into a silo, which will not be opened until about the first of July. Fodder corn will be fed from the first of November until about the first of February, when a silo will be opened which holds enough ensilage to last until the middle of May. As a rule, farmers are too busy to putter with little plots of this and that to help out in spring and summer pasture, and so we propose to set an example in supplying feed for our dairy cows by practical business methods.

We have tried to provide green feed by sowing various kinds of grain, such as rye, barley, corn and sorghum, but find them all impracticable, as cows destroy more than they will eat, causing a waste beyond all reason, and the item of cost of fencing and seeding, makes it very dear feed. Winter rye is objectionable food for a dairy cow because it taints the milk, and by the time the ground is sufficiently settled in the spring to receive the cows the pasture will be ready to receive them.

Futhermore, cows are not fond of rye, and the little they will eat of it will not pay for the destruction of a crop of rye. Cows are very found of young corn and will do well for a few days when turned into a lot of sowed corn; but since they tramp down two-thirds of it, the waste is so great that this method will never find favor among dairymen. Sorghum is not so well liked by cows, and it contains such a high percentage of carbohydrates that it requires too much mill feed to balance the ration for dairy cows. Carbohydrates are fattening and may answer for steers or sheep but not for milk cows. Sugar and starch makes animal fat but not butter fat. Oats and barley will answer a few days for soiling purposes and can be fed to good advantage from the time they head out until in the milk, when these crops should be cut for hay or allowed to ripen for a grain crop.

Our future standard cow feed is cured corn fodder and ensilage for winter and ensilage for summer, and the sooner cow-keepers adjust their farming operations to the present condition of affairs the better. We have used a fodder cutter and a silo for 15 years, and after all this experience feel warranted in stating that no farmer is properly equipped for the dairy business without both of them. We would as soon undertake to dairy without cows as to attempt it without a fodder cutter and a silo. Ensilage must be cut and fodder corn should be.—T. L. HAECKER, in *Farm Stock and Home*.

Injury to Dairymen.

Loss by Fraudulent Sale of Oleomargarine.

E. M. Slayton, of Manchester, N H., well known in the west, has issued an appeal to those interested in dairying in his state to attend the convention to be held next Tuesday (June 20) at Concord; and in this address Mr. Slayton brings out facts which apply to every state where oleomargarine is fraudently sold as butter. The Concord convention, as *Chicago Dairy Produce* has previously announced, is called to arrange plans for the enforcement of the oleomargarine law of New Hampshire, and to organize a state movement in favor of the proposed taxing by congress of 10 cents per pound on all oleomargarine colored in imitation of butter.

Mr. Slayton's letter is directed to the managers of creameries, and in it he says:

"We have a law in this state relating to the sale of oleo, also a law directing the secretary of the Board of Agriculture to enforce the same, but here in Manchester, in the month of May, 1899, the grand jury of Hillsborough County refused to grant indictments against dealers who made sales of oleo, classing the prosecutions with those against liquor dealers, thereby indicating that in their judgment the illegal sale of oleo and of liquor were on the same basis, and that the people of the state of New Hampshire did not care to have the law regarding the same enforced."

It is our humble opinion that this is not a fact. If the consumers of oleo were benefited even a small percentage, by the amount of money that is lost to the farmers throughout the state, or if the profits on the sale were divided with the people who were residents of the state and pay taxes here, perhaps it might be considered a benefit, but the fact is that of the more than $1,000 per carload profit, which is made on the sale of oleomargarine, practically none of the money stays within the state. There are only fourteen oleo factories licensed by the United States authorities, and they work together as to prices, making them just enough lower than the price of butter to secure a sale Even the distribution throughout the state has been in an underhanded way, and at a minimum of cost to the manufacturer.

A careful computation of the quantity of butter usually consumed per person in the boarding house and restaurant, shows that the consumption is practically one ounce per person per day, and the less price the boarding house keepers have bought their oleo than what sound, sweet butter would have cost them, reduces the cost one half a cent a day per boarder, or three and a half cents per week per boarder, certainly an insignificant sum to save, one which cannot for a moment stand against the reduction of $3.50 per cow to all the farmers in the state of New Hampshire, whether their milk is sold as milk or taken to the creamery and the product sold as butter.

The sale of butterine or oleo in the state of New Hampshire has increased more than 500% in the last three years, and it is our judgment that the almost unrestricted sale of the same has reduced the price of butter two to three cents per pound. Two cents per pound on butter is equal to $3 50 per cow, reckoning the output per cow to equal 175 pounds of butter per year, and as there are about 110,000 milch cows in the state, and reckoning that the product of 100,000 cows is sold off the farm, it makes $350,000 less per year to the milk producers of the state.

As you all know, the price paid by the contractors per can for milk, is governed, to a large extent, by the value of said milk to be made into butter, so we can safely say that the value of the product of every cow throughout the state is seriously affected by the sale of oleo, and unless there is something done by the farmers to lead to a change in the minds of the people, I am afraid the consumption of oleo will be larger the coming fall and winter than ever before. It certainly will be, if the grand juries refuse to carry out the laws of the state.

The statement has been made to me by people high in authority that they understood that oleo was fully as healthy as butter, but the fact is that tallow and paraffine, which are both used in the making of some, are very hard to digest and are injurious to any stomach but the very strongest.

We trust that you will make an effort to attend the meeting to be held June 20, 1899, at Concord.—*Chicago Dairy Produce*.

Importance of Corn Fodder and Ensilage.

These feeds are the most important factors on the dairy farm. Every dairyman must secure a ration that will produce milk cheaply, and experience has taught him that corn about fills the bill. The great question is how to preserve it in the best way. After 12 years of experience with a silo I have no hesitation in saying that by no other method can corn be preserved so as to give as good results. The kind for the individual farmer to grow, is the variety that will mature a fairly good-sized ear and an abundance of leafage.

In preparing the ground for ensilage crops, plow deeply in autumn. Spread manure on this plowed ground in winter at the rate of 20 loads per acre. Go over the land in spring with a disk or spring-tooth harrow, and as soon as the danger from frost is over, cultivate thoroughly with an ordinary cultivator, then roll. Plant in rows 3½ ft. apart, growing three stalks in each hill, if possible. Harrow the field twice before the corn comes through and twice after it is up. I would not advise harrowing after the corn is 8 inches high. After that use an ordinary cultivator. While the corn is growing I build the silo. The kind of a silo will depend a great deal on circumstances. If I had the material at hand to build it of concrete I would do so. If you prefer a wooden silo, a round one is best. In any case, it should be 30 ft. high. The size will depend upon the number of cattle to be kept. Silage from fairly well matured corn makes a good milk-producing ration and about 40 lbs. per animal is the average daily feed. Young cattle require less, and beef animals usually require more.

In my own case I like to feed a ration of one-third marsh hay, one-third sheaf oats, which have been cut a little green, and one-third clover hay which has been run through the cutting machine. For green feed I like peas, oats and barley, using for seed a mixture in the proportion of 4 bushels of oats, 2 bushels of barley and 1 of peas. Cows newly in milk or heavy milkers are given what they require of this feed for best results. I feed ensilage to horses, cows and calves. Last summer I built a stone silo 20x24 feet and 30 feet high, plastering it on the inside with Portland cement. Studs were arranged on the outside and the silo covered with shiplap. The air space between the shiplap and the stone is a great aid in keeping out frost. This silo holds 150 tons and has been very satisfactory.—*Joseph Yuill, Ontario*.

A RESOLUTE SET OF CREAMERY PATRONS.

The patrons of Rock Creek, Iowa creamery held a meeting recently and discussed the poor milk question, with their sleeves rolled up, as the following resolution will testify:

WHEREAS, The eastern buyers are getting more and more particular as to the quality of butter and

WHEREAS, Most of the causes of poor butter are claimed to be from tainted or bitter milk. Therefore

Resolved, That all patrons of our creamery shall be compelled to keep their milk cans clean and in good order and to strain their milk and properly cool and care for the same, and any milk that comes in dirty cans or shows poor keeping shall be classed as "B" milk (good milk being classed as "A" milk) and the "B" milk shall be sold for four cents per cwt. less than "A" milk.

HOLSTEIN CATTLE! The Choicest Milk and Butter Breed in the World. Write to Wis. Live Stock Ass'n, Appleton, Wis., U.S.A.

SHADY NOOK HERD Holstein-Friesians Two yearling bulls from dams giving 60 lbs. and 71 lbs. each. Test 4.5 and 3.6 each. W. R. GATES, Ripley, Jefferson Co., Wis.

Registered Holstein-Friesian Cattle. Best families of the breed. Aaggies, Waynes, De Kols, Netherlands, Pauline Pauls, Pietertjes. WM. O. JACKSON & SONS, South Bend, Ind.

HOLSTEIN-FRIESIAN CATTLE Owned by JONES & RANDALL, Hustisford, Wis. 100 head to select from. From families rich in butter fat. Herd now headed by Barron Paulina De Kol. Stock for sale. Prices reasonable.

HOME FARM HERD. Headed by Jewel of Home Farm, Sweepstakes Holstein-Friesian Bull Trans-Mississippi Exposition Omaha, Neb. Seventy-five head to select from. W. B. BARNEY & CO., Hampton, Iowa.

MEADOW LAWN HERD Holstein-Friesians. Herd headed by Sir Brookside De Kol. Choice young stock for sale Come and see them. C. W. HARRISON, Ringwood, McHenry Co., Ill.

OAK GROVE HERD H-F. Cattle. Cows, Heifers and Bull Calves For Sale. O. H. Stevens, Jefferson, Wis.

Holstein-Friesians MECHTHILDE BULLS FOR SALE. Address M. W. BARDEN, Portage, Wis.

McGEOCH FARM Holstein-Friesians. Herd headed by Gem Pietertje Hengerveld Paul De Kol and Johanna Paul Colantha. A few young bulls, 3 to 7 months old for sale at bargain prices. H. B. DAGGET, Mgr., Lake Mills, Wis.

HOLSTEIN-FRIESIAN BULL CALVES From advanced registery and officially tested, prize-winning dams, as high as the 21-lb. class, 70 to 76 lbs. milk from cows. Quality as well as quantity. If you want *the* best address MALCOLM H. GARDNER, Darien, Wis.

130 Holsteins. First prize herd at Trans Mississippi Exposition, at Omaha. 1st and 2nd on aged cows and 1st. on two-year-old heifer in the seven day butter test, open to all breeds at same Exposition. Three cows in this herd have produced the most butter in seven days of any cows ever officially tested. A score of others nearly as good. Our richest bred bull calves are taken young. Sons of De Kol 2d and Netherland Hengerveld head the herd. Animals of both sex and any age for sale. Write stating just what you want, HENRY STEVENS & SONS, Lacona, Oswego Co., N. Y.

MECHTCHILDE AND TIRANNIA

The two greatest cows in the world are owned at Valley Mead Farm. Their average milk record, each, is 101½ lbs. in one day; average butter record, each, for 7 days, 38 lbs. 8½ oz, an average which stands unequaled by any two cows in the world for either milk or butter. The fame which these cows have won in the show yard and public milk and butter tests, stands unapproached, like their records. They sold for $2,000 each. Their blood, which was almost unobtainable, can now be had in young males, close, through their sons and daughters Address Valley Mead Farm, Monticello, Wis.

Markham Manor Farms. Simonsville P. O., Andover, Vt. Holstein-Friesian cattle bred from the most fashionable butter families, individually large producers, and of the most approved show form. The herd contains seven daughters of Sir Netherland Soldene Clothilde, No. 18390, H. F. H. B., the most remarkable show bull of recent years. Also large English Berkshire Swine from noted prize winning and imported stock. Write for description and prices to J. A. THORNTON, Mgr., Simonsville, Vt.

GUERNSEYS AND POLAND-CHINAS. Bred from the most noted prize-winners. Calves and Pigs at bargain prices. CLAYTON C. TAYLOR, Lawton Station, Erie Co., N. Y.

GUERNSEYS FOR SALE. The increase of my herd is a few young things of both sexes, from one to eighteen months old. Prices corresponding to age and quality. F. W. TRATT, Whitewater, Wis.

GUERNSEY Cattle—SHETLAND PONIES.—Old Homestead Herd was Champion at O., Ill. and Ind. State Fairs, 1898, winning against well-known O., Pa., and N. J. Guernsey show herds. Over twice as much prize money as all competitors combined at above fairs. No better collection in America. Breeding Stock for Sale. Inspection invited. L. V. AXTELL, Perry, Lake Co., O.

Riverside Guernseys. CHAMPION HERD AT NEW YORK STATE FAIR, 1898, in competition with the leading herds of the country, won eight firsts and sweepstakes. Young stock by COMUS, sire of most of the winners, for sale. Thoroughbred Poultry—the best egg-producing and general purpose varieties—Leghorns Wyandottes, Buff Ply. Rocks, Houdans. Send for circular. Stock for sale. J. FORSYTH, Riverside Farm, Owego, Tioga Co., N. Y.

ROSENDALE GUERNSEYS. Our herd has won first prize at the Wisconsin State Fair every year since 1894, and also won first at Minnesota State Fair and at the Trans-Mississippi Exposition in 1898. We keep only 400-lb. cows. Tuberculin tested. GEO. C. HILL & SON, Rosendale, Wis.

"Florham" Guernseys. First Prize Herd wherever shown, viz: New York State Fair. 1895 and 1897; Bay State Fair, 1895; Inter-State Fair, Trenton, N. J., 1895 and 1897; Madison Square Garden, 1895; New Jersey State Fair, 1897. J. L. HOPE, Farm Supt., Madison, N. J.

GUERNSEYS! 84 Cows averaged 399 lbs. of Butter each in 1898. Some Choice Young Stock For Sale. ELLERSLIE STOCK FARM, Rhinecliff, N. Y.

AYRSHIRES Finely Bred and from the very best families. Stock for sale, bred for milk and butter qualities. Also fine herd Chester White Swine. Correspondence solicited. FRED TSCHUDY & SON, Monroe, Wis.

Rape as a Forage Crop.

"Throughout a large portion of the United States, farmers and stock-raisers could advantageously grow more of the succulent forage crops for feeding stock during th. summer and autumn months when the supply of grasses and clovers is often limited. Such crops may usually be grown on land that has already produced an early maturing crop of some sort, such as oats, rye, or wheat. One of the best of these succulent crops is rape (Brassica Napus, Linn.), a plant closely related to cabbage, turnips and several other garden and field crops.

DESCRIPTION.

"Rape is much like the Swedish turnip, or rutabaga in appearance, but the root is more like that of cabbage. The leaves are large, glaucous, smooth, spreading, and variously notched and divided; the flowers are bright yellow, nearly one-half inch in diameter; the seeds are produced in pods usually two inches or more long.

"Under ordinary field conditions, the plant reaches a height of from 1½ to 4 feet, and the strong-growing roots penetrate the soil to a considerable depth.

"Rape is either annual or biennial. The annual varieties (summer rape) are grown chiefly for the seed, and have not been much cultivated in this country. The biennial varieties (winter rape) are used largely for forage.

NATIVITY, USES, AND EXTENT OF CULTIVATION.

"Rape, like the turnip, is a native of Northern Europe, ranging eastward into Siberia. Although it has long been cultivated in the Old World, it has received but little attention in America until within comparatively recent years, and is now much more widely grown in Canada than in the United States. Practically, all the rape grown in this country is the winter or biennial sort, but in Europe, especially in England, summer rape is widely cultivated. The seed yields about 33 per cent of expressed oil, which is of value for lubricating, and is also used for lighting. The compressed rape-seed cake is used as a food for stock and as a fertilizer. It is regarded as particularly valuable as a fertilizer for flax and turnips. The seed is much used as a bird food. In this country, rape is grown almost exclusively for forage, being used chiefly for soiling, and summer and autumn pasturage.

"Rape is best adapted to rather cool, moist climates, such as prevail in portions of Canada and the northern United States. It can, however, be successfully grown as a forage crop in many of the warmer and dryer sections. Thus, in favorable seasons, or with a small amount of irrigation, excellent crops of rape are grown in Wyoming, Montana, the Dakotas, and other states in the so-called semi-arid region, and many instances are on record where good crops have been produced without irrigation, under conditions of drouth so severe as to cause the failue of corn and other farm crops. In parts of the South, rape may be grown for late fall or winter forage.

SOIL REQUIREMENTS.

"For its best development, rape requires a rich, moist, loamy soil and will usually do well on any but light sandy soils and stiff clays, such soils being usually deficient in vegetable matter. In general a soil that will produce good crops of turnips, cabbage, wheat and corn will be suitable for rape.

"Rape is a gross feeder and draws quite heavily on the nitrogen, as well as the mineral constituents of the soil, and hence should be used in rotation with crops that feed largely on other elements of plant food. For example, rape and fodder corn take about the same proportion of nitrogen, potash, and phosphoric acid from the soil, and experience has shown that corn does not do well after rape, unless the land is naturally rich in these substances. Results obtained at the North Dakota Experiment Station, indicate that the growing of a crop of rape on land that has been sown to wheat for a number of years produces a decided increase in the yield of wheat from the succeeding crop. This is a point of much value in regions where wheat is extensively grown.

VARIETIES.

"All the varieties of rape that have come into prominence in American agriculture are winter or biennial sorts. Dwarf Essex or English rape has been most widely cultivated. Recently a variety has been placed on the market under the name of Dwarf Victoria rape, or simply Vicioria rape, which has given excellent results in New England and also in the Northwest, yielding, as a rule, rather better than the Dwarf Essex. At the New Hampshire Experiment Station this variety is reported as yielding nearly 50 tons of green fodder per acre, and yields of 25 to 30 tons per acre are reported from South Dakota and elsewhere in the Northwest. Under average conditions, a yield of from 10 to 20 tons or more may be expected from either of these varieties.

CULTURE.

"Owing to the great variety of ways for utilizing rape and the many places it may occupy in the rotation of crops on the farm, there are numerous methods of culture that may be followed in growing it. When it is grown as the primary crop of the season, the land should be prepared by deep and thorough plowing, preferably early in the preceding autumn. In some soils a second plowing should be given in the spring before the seed is sown, but in soils that are naturally loose and mellow, such as are found in portions of the Northwest, a simple stirring of the surface with a cultivator or disk harrow will often be sufficient. The land should be well pulverized by harrowing before the seed is sown. When the land needs fertilizing barn-yard manure may be applied before plowing, in the autumn, or if the land is plowed twice, the manure may be spread on during the winter or early spring before the last plowing. Commercial fertilizers may be applied by harrowing in at the time the land is being pulverized previous to seeding. Whatever treatment the land is given in preparation for this crop it should be such as to afford a deep, mellow seedbed, as free as possible from noxious weeds.

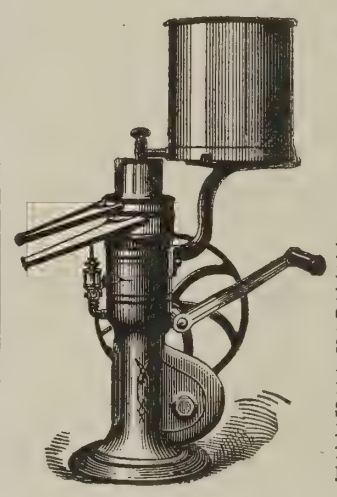
SEEDING.

"Throughout the northern states generally, seeding may take place from the first of June or possibly earlier, to the middle or last of July, according to the season and locality. In the south the seed may be sown in September or early in October. Under favorable conditions two to three pounds of seed per acre will be sufficient and it will never be necessary to use more than five pounds per acre. The seed should be planted in drills far enough apart to allow cultivation. In practice the distance varies, but it is seldom less than twenty inches nor more than thirty-four; twenty-two to twenty-eight being perhaps the most satisfactory, all things considered. For planting small fields any of the common garden drills will be found quite satisfactory, but for large fields a grain drill with some of the feed hoppers closed, may be used. When the ground is clean and in proper condition otherwise, good results may be obtained by using the grain drill with all feed hoppers open, and giving no after cultivation. As a rule, however, it will be best to plant in wide drills and give sufficient shallow cultivation to keep the soil in good physical condition and destroy weeds. With favorable soil and climatic conditions, good crops of rape may be obtained from broadcast seeding, but whenever there is any danger of the surface soil becoming very dry during the time the seed is germinating, or when land is at all foul, drilling will give much better results.

AS A CATCH CROP.

"When rape is grown as a secondary or catch crop, it will not often be possible to pay so much attention to the preparation of the soil and the time and method of seeding, and quantity of seed used may be varied to suit the circumstances. Often, fine rape may be grown on land that has already produced a crop of some of the early maturing cereals, such as rye, oats, or barley. As soon as the crop of grain is removed, the land is plowed or "disked" and at once seeded to rape. Field peas and other early maturing forage crops, or rye or winter oats that have been pastured off in spring may also be followed by rape with profitable results.

"Another practice which is coming into favor in some sections of the country is to sow rape in the spring with some grain crop, such as wheat, allowing the former to take possession of the field when the latter has been removed. This method is especially satisfactory when succulent forage is desired for fall feeding. Rape may also be sown in



The One Successful Color

IT gives entire satisfaction and is the only color that buttermakers should use. It is the one color found in over ninety per cent of the creameries of the country. Butter containing Wells, Richardson & Co.'s Color has the highest standing in the markets. . . .

the corn field just before the last plowing, as is often done with rye and winter wheat.

AS A WEED DESTROYER.

"Aside from its value as a forage, rape is an excellent crop to grow on fields that are foul with weeds. The late date at which the seed may be sown allows the weeds to get well started before the final preparation of the soil begins, they are further kept in check by the cultivation required for the crop during its early growth and later the rape plants shade the ground so completely as to keep the weeds down. An excellent treatment for a foul field, is to plow thoroughly in late summer or early autumn and seed to rye or some other forage crop to be pastured off during the fall, winter, or early spring. When the crop has been pastured sufficiently, and before the weeds have produced seed, plow again, plant rape in drills and give thorough cultivation. There are few weeds that will survive such treatment, and the land will have given profitable returns in forage in the meantime.

HARVESTING AND UTILIZING THE CROP.

The rape is usually ready for use in about 8 or 10 weeks from the date of seeding. The general practice is to use it as a soiling crop or as pasturage. Sheep and swine may be turned into the field and allowed to remain until the rape is pastured off. Cattle may also be allowed to run in the field, but as they waste much of the forage by pulling up the plants and trampling them down, it is a better plan to cut the rape with a scythe or mower and feed it to the animals.

With sheep and cattle, care should be taken at first not to allow the animals to eat too much, as there is danger of injury from bloating. Hungry animals should not be allowed to eat their fill, and it is not best to turn them into the rape when the leaves are wet. There is no danger of bloating with swine. It is an excellent plan to have the fields so arranged that the sheep and cattle have access to an open pasture as well as to the rape. Animals should have free access to salt at all times when being pastured on this crop.

FEEDING VALUE.

Rape has a high feeding value. It makes an excellent feed for fattening sheep and swine and for producing an abundant flow of milk, in milch cows. On account of danger of tainting the milk, many people do not feed it to the cows until after milking. Rape can be used to good advantage as a part of the ration for animals that are being fed in pens for market or for the show ring. It is also a valuable food for young lambs at weaning time. By beginning as early as practicable in the spring and seeding at intervals of two or three weeks, a continuous succession of rape can be produced throughout the period when the permanent pastures are most likely to be short. Rape will endure quite severe cold weather and thus will last a long time after the ordinary pasture grasses succumb to the frost. By the use of this crop, stock can be gotten into good condition for the holiday markets or for winter, and there need be no check in growth, fat and milk production, through insufficient succulent food during the late summer and autumn months, as is too frequently the case.

Under favorable conditions, two or three cuttings may be made in a single season from a field of rape grown as a primary crop. Mr. W. H. Heidman, of Kalispell, Mont., reports three cuttings the first season with a heavy yield of forage. He allowed the plants to stand the second season and obtained a fine yield of first-class seed. Not much attention has been paid to growing rape for seed in this country, possibly because of the fact that in most localities where this crop has been extensively grown, the winters are so severe as to destroy the plants. It seems, however, that there are localities where rape can be profitably grown for seed and farmers might well devote more attention to this feature of rape growing, since most of that now used is imported.—Bulletin U. S Dept. of Agriculture.

The Kansas Dairy School.

ED. HOARD'S DAIRYMAN:—The regents of the Kansas State Agricultural College have just elected F. H. Leighton, New Hampton, Iowa, Instructor in Creamery Butter making, and H. Van Leeuween, Effingham, Kansas, Instructor in Factory Cheese Making.

The Dairy School will open Jan. 3, 1900.

Plans are well under way for the new $25,000 dairy building and for the new 100 cow dairy barn. H. M COTTRELL.

To Destroy Live forever.

ED. HOARD'S DAIRYMAN:—Tell W. W. B., whose letter is on page 288, that there is a "diseased liveforever" that will kill other liveforever if planted by the side of it. Mr. Frank Hill, of this place, had a field of about two acres, literally covered a few years ago but it is nearly all gone now. The plants commence withering up the last of this month and die. E. O. D.

Swale, N Y.

REAL YOUTH.

When you see a man old enough to be a grandfather pick up a heavy trunk and march off with it on his shoulder you realize that a man may be young at almost any age if his blood contains the elements that youth is made of. That is the sort of youth that Dr. Pierce's Golden Medical Discovery puts into a man's veins. It gives him digestive power; it turns his food into good nourishing blood; it enables the liver to keep that blood pure and free from bilious poisons. It fills him with muscular strength and vitality. It makes him in the truest sense young again, and keeps him so.

"I am pretty well now, for a man of sixty-three years," says Mr. John Larson of Ashby, Grant Co., Minn. "I had been very badly troubled for many years with dyspepsia, also nasal catarrh, and got so bad and weak that I could not work.

"I could hardly eat anything without vomiting; had a pain in the stomach and a burning sensation coming into the throat. I took Dr. Pierce's Golden Medial Discovery and 'Pleasant Pellets,' and can truly say these medicines have helped me wonderfully. I commenced taking them in the fall and used them all winter. I took fifteen bottles of the 'Discovery' and six of the 'Pellets' according to directions, and must say that both are good honest medicines.

"I improved right along from the very beginning. I just stopped taking medicine in the latter part of May and then felt as well as ever in my life. I can eat all kinds of food and it dosen't cause me any pain in my stomach now as it always did before I took Dr. Pierce's medicines. I can cheerfully say to the public that they need not hesitate in taking Dr. Pierce's Golden Medical Discovery for dyspepsia; it will eradicate and cure the disease if anything will."

If you are in poor health write to Dr. R. V. Pierce, of Buffalo, N. Y. It will cost you nothing whatever for his advice although he is at the very head of his profession in the treatment of obstinate chronic diseases.

The Relation of Disinfection to the Health of Live Stock.

Its Mode of Application and Advantages.

The word disinfection to some means little, while to others it is of vast importance. By the term is meant the application of agents which prevent or destroy these living micro-organisms from which contagious and infectious diseases arise.

Disinfectants are placed under various classes, as those which kill the germ when brought in contact, those which change the material upon which its existence depends, those which absorb or encase the disease germs, rendering their existence harmless, etc.; but by the every day busy man these distinctions may be left to the investigator to dictate to the world which is most suited to each and every particular necessity. There are, however, in common, certain conditions necessary to each and every individual who has the responsibility of avoiding or combating diseases to which animals subjected to his care, are or may be exposed; and perhaps, the greatest of all responsibility rests with this class, for no place can be free from germs where there is absence of good sanitary arrangement, cleanliness, pure air, sunlight, perfect drainage, etc., in the presence of which artificial agents need be called very little into use. There are, however, conditions surrounding the live stock breeder to day for which he is not entirely responsible, as, for instance, the outbreaks of hog cholera at different points, and the generally distributed outbreaks of contagious abortion among our Canadian herds of cattle, which in certain sections are becoming alarmingly prevalent and doing inestimable damage. Either of these may be brought entirely within control by the exercise of proper disinfecting treatment. No definite rule can be laid down to meet the requirements of each case; yet in the main, cleanliness and the absence of decomposition must be first considered under all circumstances, as the heaping of disinfectants on dirt cannot bring sweetness and purity. It must therefore be remembered that disinfectants should never be allowed to be made an excuse for habits of carelessness or uncleanliness, but all refuse and dirt should be removed regularly, and no accumulation of such permitted. Sweetness is health; stench is disease. This being accomplished, we have many highly useful agents within our reach, and our object now must be to select those agents possessing the greatest antiseptic with the least objectionable properties. All disinfectants are more or less poisonous, and the more powerful in antiseptic properties the more destructive to all life. Therefore for our purpose much caution must be exercised in their selection and mode of application.

Corrosive sublimate is perhaps the most powerful of all antiseptics, yet from its extremely poisonous action its application is attended with too great risk to the subjects we wish to protect. Carbolic acid ranks high, if not among the highest in this class but its corrosive and death-dealing effects are so positive that its application demands the greatest of caution, and is therefore not safe in the hands of careless operators, and therefore should not be employed in concentrated form. It is, however, highly useful when protected in dry substances, which render their liability to be taken in overdoses impossible. Chloride of lime, although yielding germ-destroying gases, while reasonably safe, is highly undesirable on account of its unpleasant odor. The coal-tar series yield, perhaps, as safe, and desirable agents, as have yet been produced, being positive in their action, attended with very little danger to human or animal life when reasonable care is exercised in their application, and give off little or no objectionable odors. These are highly destructive to the lower forms of germ life when brought into contact with it. Of this class, creolin is perhaps the basis of many of the best and most desirable products now on the market under different names and offered for disinfecting purposes. Many of the advertised sheep dips and cattle washes owe their virtues largely to this class of products, and are perhaps the most valuable yet known, as they contain many desirable and few objectionable and dangerous properties.

Having selected our germicide, the next step is to consider the mode of application and conditions necessary to obtain the best results when applied. First remove all dust and filth, sweep down all cobwebs—and right here let us add that it is deplorable to walk into an expensively constructed stable and find the ceilings hanging thick with cobwebs, when so little exertion is required to remove and destroy them. What owners neglect, herdsmen should see the necessity of doing, and the attendant who has to have his attention drawn to such details is lacking in the qualities which should bring him to the front. After all dirt is removed and due regard is placed upon cleanliness, light, drainage, ventilation, etc., the thorough application of the agent to floors, walls, ceilings and drains should follow. It should be evenly distributed if in powder, or if in liquid form the modern spray pump is a splendid and economical medium, some of which have special provision for this work. Among the more prevalent diseases to be combated by the use of disinfectants, we look upon contagious abortion as worthy of our first consideration, and to our mind this is one condition the eradication of which wholly depends upon proper, thorough and persistent effort; in fact, the disease could not gain access in the presence of proper disinfecting agents.

Hog cholera, so prevalent and destructive in certain sections, can at least be held in check, if not altogether prevented or eradicated, by its thorough application. The germs of lump jaw, so prevalent in cattle in certain sections, are given off in abundance in the saliva in feeding trough, there to remain to attack the first victim accepting it, and may be destroyed by proper application of disinfecting substances. Ringworm may easily be eradicated from the premises, as its presence depends upon a vegetable parasite. Lice and other vermin on horses, cattle, sheep, pigs and poultry require direct applications to the skin of the animal, yet much valuable assistance would be added by thoroughly disinfecting their places of abode. Even worms in sheep, pigs and calves would find far greater difficulty of existence during their transitory stage in disinfected quarters. Much may also be done to reduce the risk and danger of exposure to many of the deadly diseases which have worked destruction in many parts of the earth during the past, which might at least have been held in check, had they not been regarded as mysterious. The advance made can scarcely be referred to better than in the following extract from the pen of an English pharmacist in a London journal:

"The useful science of bacteriology is indeed full of surprises, and every year bears witness to the astounding strides with which it grows, whilst day by day it is being more widely recognized of what stupendous importance to man is the message which it has to deliver. During the earlier childhood and adolescence of this new science, it was generally believed that this message was of a gloomy character, and one which it would be better to leave untold, for to the public it seemed as though it had nothing but death and destruction to reveal as lurking where danger was hitherto unsuspected. For many years bacteriologists had apparently nothing to announce but the discovery of new and subtle enemies to mankind, and to produce poisons possessing such a degree of malignity that beside them the venom of snakes and the most potent drugs of the apothecary appeared as comparatively harmless and even friendly. In reality, however, these deadly foes and poisons have always existed before, and have wrought their lethal work in the dark until exposed and branded by men of science, who after years of patient labor are now teaching the world how these foes may be vanquished, and how these old, but until recently undiscovered poisons may be counteracted and rendered innocuous by the administration of new antidotes."—*Farmers' Advocate.*

When the Cow is With Calf.

ED. HOARD'S DAIRYMAN:—I note in your issue of June 9th, an inquiry relative to the sign of a cow being in calf. I would say in reply to I. G. McC. that in Beech Hurst Herd we depend always on the following method:

The cow to be tested is of course milked separately and as soon as possible after milk is drawn, we dip a straw or timothy stem in the bucket of milk. Have a glass of pure water at hand and allow one drop of the milk to fall in the water—only one; if the milk quickly dissipates and renders the water murky, she is not in calf, but if the milk drop sinks to the bottom of the glass before mixing with the water, she is pregnant.

If you are not sufficiently expert, take the milk of another cow that has newly calved, and pursue the same treatment with both, at the same time, and you will not fail to note the difference in the way the drop of milk will mix with the water. I have practiced this method of determining pregnancy in my herd for years and I never knew it to fail.

Of course, I only speak from my own experience, but the theory is that the milk of a pregnant cow is viscous, or has a sticky adhesive quality that causes the particles to cohere more closely; consequently the tendency to drop in a mass instead of mingling immediately with the water.

I usually take the morning's milk for the test and use cistern or rain water, if you have it, or better still, filtered or boiled water. On "Beech Hurst" we have three kinds of water, pure spring, cistern, and slightly mineral from a tubular well, but always prefer cistern.

Impure Water.

The dirty brook should be a theme for thought by more than one dairyman. The man that has no running brook on his farm is more likely to have good water for his cows than the man that thinks he is blessed by a stream of running water. Where the stream is rapid moving and fairly deep, it may serve for a drinking place the year round, but in most of our western states the conformation of the land is not such that a stream is either swift or deep or clear. In states that are filled with mountains and hills and forests, the streams, to a large extent, remain pure the year round. The soil on their banks is held in place by a multitude of vegetable growths. Frequently they run over a bed of stones, and are little exposed to impurities from the immediate banks. Such brooks may, in mountainous localities, serve as a suitable drinking place for the cattle most of the year, or until the summer drouth renders them stagnant. But in this great level country of the west, conditions are different. The ordinary brook should never be depended on as the water supply for the cattle. There are few times in the year when it is safe for them to drink from it, if the dairyman wants to keep both animals and animal products pure. In the midsummer especially it is a positive detriment to the dairy business. The man with the slimy, muddy brooks too often neglects to have a pure water supply, which his brother farmer, who has no brook, is compelled to supply. We have seen such streams in summer become muddy wallows where the cows both stood and drank. There is no doubt that animals, like humans, contract many diseases, solely through bad drinking water. On many farms the conformation of the land is such that shallow streams may be made sanitary by deepening the central channal and sinking a few shallow wells in their beds at various places, if the pasture is so large that the cattle would have to travel a great distance on a hot day to get water.—*Farmers' Review.*

Prepotency in the Bull.

The New Jersey Experiment Station has a herd of forty cows. The milk is sold at retail and guaranteed to contain four per cent of fat. It is useless to make any such guarantee unless the cows are good ones. The bull at the head of the herd is a Guernsey, and there are Guernsey, Jersey, Holstein, Ayrshire and native cows. They are all good ones. An old dairy farmer came into the barn and looked them over. His comment was:

"Have you any heifers for sale? I will take one from any cow in the barn, for there isn't a poor one here!"

Prof. Voorhees likes the Ayrshire cows. They are strong and hearty, good eaters, giving a good mess of fair milk. He would not keep all Ayrshires and guarantee four-per-cent milk. The Holsteins in the herd give lots of milk, but it must be enriched and colored with Guernsey or Jersey milk to fill the bill. The Guernsey is the great color bearer. One Guernsey to half a dozen Holsteins will help out the mixed milk wonderfully.

The old Guernsey bull at the Station was a good one, and he put his color and shape on most of the calves. The Holsteins, however, are too strongly prepotent for him. They dropped calves like the bull in shape, but with the black and white color. The Holstein is one of the oldest of breeds. Its color and shape have been bred for centuries, and are fixed traits. The golden color of the Guernsey was not so strongly bred into the bull, and the black and white color prevailed. The younger bull, however, is more prepotent. His calves, out of the same Holstein cows, have the Guernsey color as well as the characteristic shape. It is a strong illustration of the difference in breeding. The bull takes what his ancestors gave him, and gives it to his calves The young bull had stronger blood in his pedigree than the old one had.—*Rural New-Yorker.*

CONCERNING OUR ADVERTISERS.

We are publishing, on another page of this issue, an advertisement of the American Hay Tedder, which is manufactured by the Ames Plow Co., of Boston, Mass. Unlike most machines of this class, the American is not operated by the angle or crooked shaft, but the forks are placed upon a revolving cylinder. It thus avoids the shock, jar and consequent wear and breakage incident to the "kicking" motion. It turns and stirs the hay thoroughly. Write these people for a catalogue before you buy a tedder.

A FEW TIMELY POINTERS.

The up to-date farmer has learned the wisdom of doing his own thinking, and in selecting a binder or mower to weigh carefully the actual points of superiority, and to avoid mere "talking" or "selling" points. The "life" of a machine depends largely on its main frame, which should be solid enough to outwear the working parts, and yet not heavy enough to tear itself to pieces through its own inertia. The Deering Ideal Binder has a high carbon steel frame, hot-riveted at the joints. This machine has stood the most severe tests ever put on a binder. It has a cutting apparatus that will cut any crop that grows; elevators that will elevate anything it cuts; a simple reel with greater range of adjustment than any other, operated with a single lever; the famous Deering Knotter and Binder which never misses; the only bundle carrier worthy of the name, and finally Deering Roller and Ball Bearings, making it the lightest draft binder that ever cut a swath.

VETERINARY.

Queries in this department answered by Wm Horne, M. D. V. S., Janesville, Wis.

Cow Physic—Three-fourths to 1¼ pounds Epsom Salts (according to age and size of animals) and two ounces of best ground ginger. Pour over this three pints of boiling water. When at 105° F., give gradually as one dose.

BLINDNESS IN COW.

I have a cow that commenced to get blind about three weeks ago, and soon ran at the nose; about a week ago she came it; she does not give hardly any milk and her teats are very sore. The discharges from her nostrils were yellowish at first and smelled very badly, but after I syringed with carbolic acid it got whiter and less offensive. We keep her in the barn. She is nearly blind.

Pine River, Wis. H.

ANSWER

I believe your cow to be in a dangerous condition and my honest and best advice to you is, to get some competent person to make a critical and close examination. This too without delay. The milk is quite unfit for use. I may be somewhat too much alarmed in the case. I hope so. Still you will do well to take my advice at once.

LOCK JAW.

My farm hand was breaking some ground June 6, and he said one of the horses got the thumps, as he called it, but got all right again. The horse eat heartily the next morning and plowed until about 10 o'clock, when he got to thumping again and staggering. He was then as wet with sweat as though he had been in river, back arched as a cow in a blizzard, great restlessness, could not keep him still a moment, left hind leg partially paralyzed so that he had to swing it outward to step, in place of bending at hock; difficult to keep him on his feet, staggers as he walks; seems to be suffering great pain or crazy or both. He got down in about half an hour, and then I more particularly noticed his respiration. His inspiration was sudden, accompanied by a loud thump, as of a sledge hammer inside of him, and a heaving of the flank and a jarring of the belly, and a spasmodic contraction, jerking and quivering of the muscles. His hind legs both became stiff and rigid toward the last, and his breathing snoring, and though we bled him and chloroformed him and used ice on his head, none of it broke the spasm and he died with his jaws tightly set.

Mount Clare, W. Va. O. T. Hansford.

ANSWER.

Your horse died with lock jaw. This was no doubt induced by the excessive heart action. The cause of this I am quite unable to state. Usually such condition is the result of hereditary origin. This I have found to be the case in many instances in the horse. My son had one die not long ago from the same cause, excessive palpitation of the heart. Against my repeated advice he drove him to a buggy, and he dropped dead in the road. In all such subjects, it takes but little excitement of any kind to cause death.

HEIFER WITH COUGH.

I have a heifer that has a very severe cough. She has never been well since she had a calf about a month ago; the calf came dead. She seems to be very sore and coughing seems to cause her great pain. She eats very sparingly, and is losing flesh all the time. H. A. W.

Sutherland, California.

ANSWER.

Lobelia, *fluid* extract two drams, gelsemium *fluid* extract half a dram, clarified honey one tablespoonful, mix and place upon the roots of the tongue, for one dose. Then, after this, add warm water, four tablespoonfuls, and allow this to trickle down the throat as slowly as you can, one dose each day for two days, then once every third day for two doses.

I would advise you to have some qualified veterinary surgeon examine the animal. She is suspicious of tuberculosis.

GARGET.

We have a valuable Jersey cow that is just fresh now that has always been troubled with garget off and on. G. A. W.

Dayton, O.

ANSWER.

It is imperative that the heifer be thoroughly milked, always. Lack of clean and perfect milking causes many udder, and other complaints of the milk process. Immediate full dose of physic and repeat once or twice if needed. Rub the udder with strong tincture of camphor six parts, and common turpentine two, only, parts. Use much gentle massage. As an adjunct, give two drams of fluid extract of poke root every third day up to 4 doses. Give good exercise daily. Rub udder twice first day, then only once for four times.

STRINGY MILK.

We have a young cow that was fresh last year, in August. Her udder will swell and she gives stringy milk for one or two milkings; then all is right again for two or three weeks. This has been so all winter. S. N.

Marble, Pa.

ANSWER.

Nothing will act so well as a permanent cure as intelligent depletion by one to three full doses of physic, about four days apart. Each morning give two dram doses of nitre, from ten to thirty days if needed. Keep away from all offensive matter, as many similar cases are the result of eating objection able stuff. Many similar cases are the result of hard jerky milking. Always avoid this bad habit.

CANCER cured at home. Send four cents, stamps. 80 page book, illustrated Dr. J. B. HARRIS, 2226 Kemper Lane, Walnut Hills Cincinnati, O.

Milk Fever CURED by the Schmidt Treatment. 90% of cures in first 412 cases. Simple and effective. Two complete treatments packed ready for instant use. For sale only by Gardiner Bros., 220 E. Preston Street, Baltimore, Md.

ABORTION!

Retention of Placenta and Failure to Breed.

H. W. KELLOGG'S experience with and positive cure for these diseases in cows. Send for circulars. Address all communications to

Fleming Bros., chemists, Union Stock Yards, Chicago, Ill.

ILLUSTRATION.

We take pleasure in illustrating this week the new Semi Circle or Swinging Carrier, manufactured by the Smalley Manufacturing Company of Manitowoc, Wis., which they present to their customers as the most strictly up-to-date Silo Carrier or Elevator ever made in this country. It is made to deliver at any point within a radius of a complete semi-circle. It is simple in construction, and yet every part of it so strong as to reduce wear and breakage to the minimum.

One of the special features is its construction to prevent any of the cut fodder or ensilage from littering the floor while at work. In fact, with this carrier, the machine can be run during a wind storm without any danger of any inconvenience or delay. As stated in their catalogue, the practical experience of this company is second to no other concern in the United States in the manufacture of silo machinery, and they assert, without any fear of successful contradiction, that they have secured the *Ne Plus Ultra* of a Feed Cutter Carrier in their 1898 Semi-Circle Carrier.

This carrier has been in practical use for two seasons and has demonstrated everywhere that it possesses marked advantages over any similar device yet placed on the market. The unusual favor that has attended its introduction has decided the company, notwithstanding the increased cost of its manufacture, to furnish it on all their Smalley Cutters at the same price as their Common Style Carriers.

Catalogue giving full description and detailed information will be mailed readers of the Dairyman upon application.

The Holstein-Friesian Meeting at Buffalo.

ED. HOARD'S DAIRYMAN:—Great interest was shown by all present in the work of the dairies owned by the members. Mr. S. N. Bright, of Elgin, Ill., who has had a tilt with the condensing factories in his district, secured a vote directing a copy of the reports of tests to be sent to all such establishments in the country. He said some people had a way of scouting all statements made by him as to the tests.

Mr. Wright was in the movement to test Holstein Friesian cows at the Chicago Fair, and led the proposal in this meeting to prepare for competitive tests. He counseled giving long time, so that nobody could make an excuse to drop out on account of lack of time.

The report of Supt. Hoxie on official tests of milk and butter fat was very voluminous, giving tests made by various experiment stations of 200 cows classed in 7 groups according to age. The Sweepstakes prize of $50 was awarded to Gillett & Son, of Rosendale, Wis., for the five cows that would have taken the most money, but for limitations. This firm also received the highest prize of $40 in class 2, cows from 4 to 4½ years old (cow Johanna Aaggie, 36477); also in class 7, cows under 2½ years (cow Johanna Rue 3d, 42167).

The tests show the highest per cent of fat to have been given by Duchess of Ormsby, 16004, owned by W. H. Jones, of Hustisford, Wis, 6.3 per cent. As is often the case the amount was not large, so the highest award in this class, 5 years and over, went to Henry Stevens & Son, Lacona, N. Y., (cow Belle Klondyke, 13913,) which gave 509 8-10 pounds of milk in a week, the highest average fat being 5 per cent.

Supt. Hoxie states that the association is convinced that the economic test is the proper basis for calculating the basis of value and more attention will be paid to it hereafter; making it foremost as soon as possible. There was some discussion of the rules to be laid down in making economic tests and it was suggested that butter fat be rated at 25 cents a pound. When the value of the milk without the fat came up, Prof. Wing said it was not easily determined as our present testing apparatus would not show it very accurately.

There was an air of confidence manifest in all comment on the standing of Holstein-Friesian cows, the tests having made such a fine showing and especially as all were conducted by disinterested experts. There was no dissent to the proposition to lay claim to the best dairy cow and stand or fall by the result. If other breeders stay out first place will be claimed.

In the report of economic tests, of which 20 were made during the year, Aaggie Paul, 40930, age under 3, stood 1st,—having produced 16 pounds 4.6 ounces of butter at a cost of 4.4 cents per pound. She is owned by W. S. Carpenter, Menominee, Mich. The largest amount was produced by Calamity Jane, 22 pounds 5.2 ounces, but at a cost of 7.04 cents per pound. Cow owned by A. & G. Rice, Curries Crossing, Ont.

Buffalo, N. Y. JOHN CHAMBERLAIN.

Training Heifers For The Dairy.

At a recent meeting of a farmers' club, a noted farmer asserted, and no one disputed, that the first calf of a heifer should never be allowed to suck as she should, in her training to be a cow, not be allowed to know that hand-milking is not the only way to relieve the udder. Then holding up her milk and the usual trouble in changing from calf-sucking to hand-milking would largely disappear, for by the milking plan she associates the milker with the maternal instinct, and her affections go to the milker, instead of to the calf; she will then be a better cow, having a better liking for her owner, as she never has had her first affection placed on the calf and then had that affection suddenly ruptured.

There is probably more in this matter than one would admit at first thought. It is a fact, quotes a writer in London Farm and Home, that the maternal affection of a cow is largely increased by the act of the sucking of a calf. A calf, when born can be placed at its mother's head, and will be duly caressed and licked; but if never allowed to suck, the cow soon tires of the caressing and in two or three days she shows no concern if it is removed, whereas, if the calf is allowed to suck for three days or a week there will be more or less of a scene when it is removed. The idea is that the calf is quite as well fed if the milk is drawn from its mother and given to it; also that if treated thus the heifer will only associate milk-giving with hand-milking, and the quiet, careful, and painstaking milker will in every way be regarded by the heifer as a perfect substitute for her calf. In this matter of establishing friendly relations with the heifer, Professor Robertson would have the heifer put with the regular dairy and be made a cow of for at least three months before she drops her calf, put daily in her own stall and be given a little extra food. He would make the stall home to her, groom her, handle her udder carefully, and treat her kindly. Such a heifer will give twenty per cent more milk the first year than another with which these relations have not been established. He would commence to train a heifer six years before she comes in milk. This means being good and kind to her mother and well feeding her, as he is sure that heredity goes along other lines than milk production.

Students of the laws of heredity, long since discovered that where animals of mixed breeds are crossed promiscuously together, there is a constant struggle of Nature to revert back to a fixed type, and generally that type which is common to the ancestry of most animals in the pedigree of the youngster produced; but as blood influences do not always accord with the arithmetical ratio of the blood itself, that is not always the case. This tendency to revert to a previous type has been seized upon by breeders as a means of establishing breeds, by thorough inbreeding of the blood of some one or more animals, possessing the type it is desired to fix upon the breed. Colling commenced with the bull Hubbuck, and he and his successors established and perfected the Short-horn breed of cattle, which continues to breed true to the established type, when kept pure, and, when crossed, struggles to assert its type. The true theory of inbreeding is little understood by the superficial breeder. An animal may possess the blood of a given ancestor without possessing the least appreciable evidence of it in its tendencies and traits—in fact, may be the counterpart of some other ancestor or bear the stamp of a group of ancestors. Inbreeding by means of such animals will not tend to fix the type of the desired ancestor or his descendants. It is not this alone that separates lines from a common source. That being the case, each will help and support the other in nature's struggle to cast back to the type. When there is strength enough in this united effort it prevails, not only in reproducing the type sought, but it eradicates contending influences and makes a prepotential individual, or one that is practically thoroughbred in type. In reproducing animal nature, blood influences have their affinities and repellants, just as we find the same in chemistry of material nature. Every student of pedigree has noticed that a typical strain from a superior source has usually a tendency to nick well when coupled with a kindred line from the same fountain.

The control which cows can and often do exercise over the flow of their milk is well known to all who have had to do with their care and management. This power, it would appear, is possessed also by the rest of our domestic animals. It is amusing to see a sow about to give her numerous family their breakfast. Having conveniently laid herself down, each of the little ones, with some bustling, lays hold of a teat and tugs and squeals with no satisfactory effect. This goes on for some little time, while the old sow gives certain admonitory grunts, and having waited till each little pig is settled and ready, she allows her milk to flow; the squealing instantly ceases, and you know they are getting their ration. Not only can a cow exercise like control over the flow of her milk, but—which is of almost equal importance—her good temper and state of satisfaction or otherwise, affect very considerably the quantity of butter fat her milk will contain. Being in a strange place, frightened, worried, made angry or subjected to ill-usage, all tend to reduce, not only the quantity, but the richness and value of her milk, for it must be remembered that a large proportion of the milk a cow gives is secreted during the time of milking. A badly or roughly milked cow will not only give less milk and poorer on any one particular milking, but such milking or milker will tend to reduce the value of the cow, if constantly subjected to it. She will give less aud poorer milk and dry up a month or two sooner and be a poorer milker next season. In many large cheese-making dairies, the owner, as a rule, always attends the milking, and no shop walker in a large drapery business looks more vigilently after the serving of customers than he watches the treatment of his cows. Unusual noises, laughing, loud talking and bustle are to be avoided at milking time. It must be remembered that the large quantity of milk given by our cows is the effect of domestication and breeding. In their natural state, cows produce about enough milk for one calf. Our best cows will well support two or more. Therefore, like all other valuable qualities produced by breeding under domestication, this increased milking habit will deteriorate under bad management.—*Ex.*

How the Horn Fly Affects Milk Yield.

John Judson of San Pasqual, San Diego county, writes to the Escondido *Times* about horn flies in a way to interest many of our readers in other parts of the state who are troubled with this grievious pest. It is a well known fact, and has been proved time and again both by our experiment stations and by many of our progressive dairymen, that anything that tends to irritate a milch cow will not only cause a marked decrease in the quantity of milk she will give, but will have a much greater effect in lowering the per cent of butter fat in the milk.

Let anyone try the experiment of milking and testing the milk of a cow under normal conditions for one day; then let the same cow be fed and watered on the next day the same as the day before, but otherwise treated harshly by whipping or dogging or any other treatment that will cause much irritation or excitement. Then test the milk, and in nine cases out of ten the milk will test from ½% to 1% less in butter fat than the day before. All dairymen know that a good and kind milker will earn his wages over and above a milker who will kick and pummel his string of cows, in the increased amount of butter fat they will give in their milk.

The Horn Fly—During the last three or four years a pest has appeared in the dairy herds that is causing greater annoyance and irritability than all the dogging and abuse the cows ever got before or since, and that is what is called by some the "horn fly." They look very much like the common house fly, but when caught are found to be very hard and firm and hard to kill. They attack a cow in such places that she cannot drive them off with her head or tail, generally on the udder, under the flank, on the shoulders and neck, just behind the fore legs and on the belly. A cow will lick the places where they bite, to relieve the irritation, till it bleeds. It will become very sore and very often ulceration will set in. The season of their worst attack is in April and May. During the last month the per cent of butter fat in the milk of my patrons has decreased to the amount of from 3-10 to 6-10 of 1%.

There has been some vigorous kicking on the part of some of my patrons on account of the low test of butter fat in their milk. I found by inquiring of my dairymen that the proportion of butter manufactured, according to the test, was the same as usual. I know the feed in April was better than in March, and that some of the herds had no fresh cows; that there was no increase of milk and still there was quite a decrease of butter fat. I could not account for it until I examined my herd of cows and found many of them suffering from the attacks of the horn fly.—*Pacific Rural Press.*

Don't Let Cows Get Tired.

Remember that if a cow is compelled to travel back and forth over a thirty-acre field from morning till night in order to hunt a ration for herself she will not give you big pay in the pail. If she has to use the energy to secure a living that she should have expended in elaborating milk, she cannot be profitable. To do her best, the cow should be enabled to fill up well in a few hours and rest the balance of the time, as it is during the rest spells that she is grinding out your profit. There is some profit in summer dairying, but we must give very careful attention to all the details, if we would realize it.—L. W. LIGHTLY, in *National Stockman.*

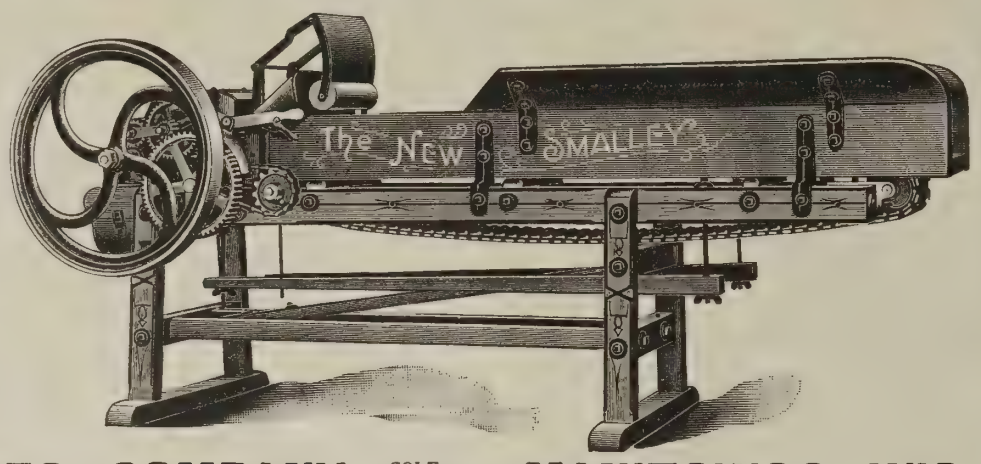
Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehensive from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be referred to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price, $2.00.

THE NEW SMALLEY



The most Up-To-Date Silo Cutter On Earth.

Smalley Cutters

For 1899 are more complete than ever before. They will be furnished, if desired, with Patent Automatic Self-Feed, **increasing capacity greatly and diminishing labor of feeding nearly ONE-HALF.**

Nos. 16, 18, 20 and 26.

If your dealer don't handle them, write for '99 Catalogue and get **SPECIAL Introduction PRICES on the SMALLEY LINE COMPLETE.**

SMALLEY MFG. COMPANY., SOLE MAKERS, **MANITOWOC, WIS.**

EVERY DAY IN THE YEAR. MOST MEN will pay $125 for a twine binder or a corn binder, machines that can only be used a few days in the entire year, and think nothing of it.

The Kemp Manure Spreader costs much less than that, and can be used successfully **every day in the year.** It will earn the interest on the money every day it is used. Spreads all kinds of fine and coarse manure, wood ashes, lime, salt, etc. Spreads broadcast or drills in the row. We make a special drilling attachment for this machine, which is of unusual value to tobacco and cotton planters and southern truck farmers. Splendid new catalogue FREE. Tells all about it.

Kemp & Burpee Mfg. Co., Box 46, Syracuse, N. Y.

DO YOUR OWN... GRINDING With one of our **FARMER'S FRIEND Sweep Feed Mills,** and save cost of hauling. It has adjustable force feed, steel ball bearings, burrs 30 in. diameter and self-sharpening. **We make Well-Drilling Machinery.**

Your Full Privilege.

Most men do not live up to their full privilege in the conduct of business. This is no less true of the creameryman than of other business men. It is your privilege to employ only the best machinery and the best methods in your business. It is your privilege to make only the "top-'o-can" "gilt edge," "extra select creamery" butter. The kind that makes the dollars bringing reputation, for yourself and creamery. Much,—very much, will depend upon the kind of separator you use in your creamery.

Sharples Tubular Separators

have almost invariably increased the yield of butter in a creamery over and above the best that was being done by separators of other manufacture. Such increase has been sufficient to pay a liberal percentage of the whole cost of the machine.

In addition to this increase in product, are the further advantages of safety; economy in oil; economy in repairs; large actual aud reserve capacity; quality and churnability of the cream; smoothness and absolute freedom from ropiness and bitter froth in the cream and the resulting improved quality of the butter.

Our knowledge of the Sharples Tubular Separator in superiority of construction and working ability is such that when requested to do so, we gladly place them with the most exacting buyers, or with the users of any other make of separator in existence, and guarantee superior results in clean skimming and in the quality of the product.

Of course we should not make such a liberal and sweeping offer if it were not fully justified by past and present results. Take these things into consideration while you are reading this advertisement. Meditate them, and then write us.

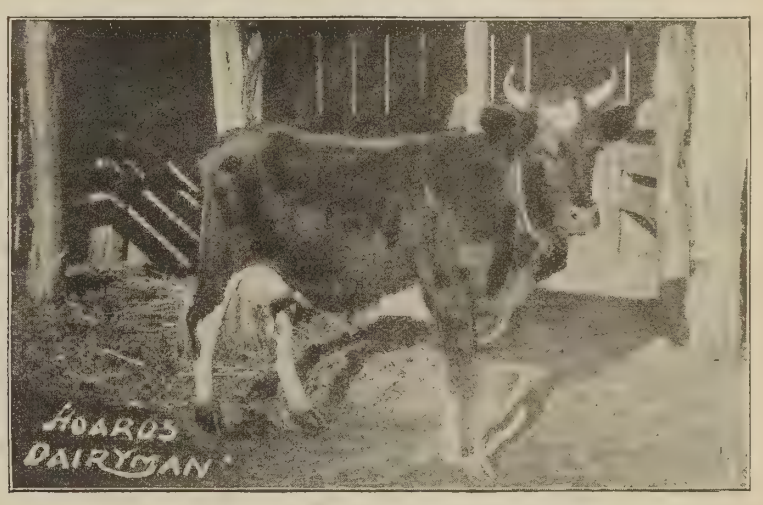
from each county in the state; also to one person from each of the first, second, third, fourth, fifth, sixth and seventh Congressional Districts, being the Chicago Districts. It is also provided that these scholarships be awarded by the Executive Committee of the Illinois Farmers' Institute.

To receive one of these scholarships will be an honor worth striving for aside from its money value, and its award will encourage many a farmer's boy and girl to work for a higher education, which they might not otherwise hope to attain.



Those wishing to apply for this scholarship or desiring further information in regard thereto, should write to A. B. Hostetter, Secretary of the Illinois Farmers' Institute, Springfield, Illinois.

THE comfort of the cow is just as necessary a factor of profitable fat production as the food is. If you don't believe it, ill treat your animals, leave them out in the cold rains in spring, and the hot sunshine of a shadeless pasture. Drive them up to the barn with noise and shoutings, and see what the effect is on the fat yield. "Treat a cow as you would a lady", said Hiram Smith. He did not say this because it was a self evident truth that was patent to everyone, but because, as the result of long experience, he had found that care and comfort of and kindness to a cow are returned many fold. If there is no other

GRADING UP THE DAIRY COW.

The advisability of grading up stock and getting a better return for the food has often been advocated by the DAIRYMAN. Facts and figures have been quoted to show the advisability of such a line of breeding.

In many cases we know that good and profitable returns have been obtained by following such advice, but it is evident that what has been done thus far is but a small percent among the multitudes of unprofitable cows. We wish, therefore, to call special attention to the pictures and communication presented on this page of the DAIRYMAN, as an excellent example of the profitable results to be obtained in a few years, by grading up from a common native cow.

The Influence of a Thoroughbred Sire.

ED. HOARD'S DAIRYMAN:—Some time ago I noticed in your paper a request to hear from your subscribers who had graded dairy cows. I herewith enclose you photographs of four generations, showing what can be done with common stock by using thoroughbred sires.

The photographs are as follows: No. 1, Spot, a common Texas cow, used constantly as a milk cow from the time she had her first calf. She gives three gallons of milk per day when fresh, but her butter is white as lard, and though she has had the same food, shelter and attention given the Jerseys, I have never succeeded in getting her to re-

GRADE JERSEY HEIFER, PATTY.

Property of Mrs. W. G. HUGHES, Hastings, Texas.

No. 3 Martha's daughter, Pansy, sire Florentino 30039 as above, gives 25 to 29 pounds of milk per day with second calf She is as persistent a milker as her dam, but her milk is much richer, tests 6% by Babcock, and her butter is deep yellow in color, quite as yellow as that from registered Jerseys. Her picture was taken just before

SCHOLARSHIPS IN THE COLLEGE OF AGRICULTURE.

At the request of the Illinois Farmers' Institute, the trustees of the University of Illinois have granted a free scholarship, good for two years in the College of Agriculture of the University of Illinois, to one person

reason for treating an animal kindly, and looking after her comfort, do it for the sake of your pocket-book, and the cow will see that it is well filled.

A Second Crop, and Milk Fever Inquiry.

Ed. HOARD'S DARYMAN:—Have a crop of oat and pea hay that will soon be ready to cut. Is there anything that could be sowed on the ground after taking off the hay that would make another crop of fodder to harvest?

As a precaution against milk fever, do you recommend that all cows be given salts as recently described in the DAIRYMAN, or only those cows that are going to have milk fever! G. L.

Adams, Wis.

A crop of millet might be sown on the pea and oat ground, and if the weather is moist, so seed is sprouted quickly and frosts do not occur in September, a fair crop of millet hay can be cut. As a rule, however, all spring grains do not grow quickly when sown in summer. Answering your last inquiry will say that the physic spoken of in the article of Valancey Fuller, is administered to all cows that are heavy milkers when they come fresh. If the cow gives indication of giving a large flow, give her the physic. We can hardly tell which cows are going to have milk fever, but it rarely if ever attacks a cow which is a light milker when fresh.

THERE are 11,000,000 butter cows in the country producing 1,375,000,000 pounds of butter per year. This is at the rate of 125 pounds per year for every cow in the country. A cow to pay for her food, should produce at least 200 pounds of butter per year. According to the above figures there must be millions of cows in the country that do not pay for their board, that go through the motions of making milk and butter only to bring their owner in a loss at the end of the year. How many of the DAIRYMAN readers are assisting to pay that board bill? And how long are they going to keep it up?

A PROFESSOR writes to the *American Druggist*, stating that he was afflicted with acid indigestion, which was cured by the use of formalin. Also, that he has taken the same chemical during different times without any injurious results, and that, therefore, formalin is a harmless food preservative. This is an excellent sample of the partisan method of reasoning, used by some scientific men.

Apply the same principles to other drugs, and lead, sulphuric acid, arsenic, opium, strychnine and many other drugs and poisons would be pronounced harmless, although experience has proven that these articles are poisons.

It will take more than a professor with a sour stomach to convince us that a chemical with the properties of formalin is a useful, necessary, or harmless adjunct to our daily food.

THE TEN CENT BUTTER.

Colonel L. S. Hardin writes very clearly and pertinently in another place on "Butter Making for the Small Dairy." What the Colonel says is all true, too true. But here is the rub. Not one in a hundred of these women who make this cheap, poor ten cent butter, or her husband, will ever subscribe for a paper like the DAIRYMAN and earnestly set to work to learn how to do better, and thereby make a better profit on the butter she makes. There is a great mass of such farmers and their wives who think every dollar they spend for such information is thrown away. Yet they go on year after year making this grease butter and losing a hundred times what the paper costs, and do not know it. It seems sometimes that though, "An Angel came down from Heaven" they would not listen.

WHICH POISON WILL YOU TAKE?

Borax.
Boracic Acid.
Sodium Bicarbonate.
Potassium Nitrate.
Hydrofluoric Acid.
Sodium Fluoride.
Sodium Fluor-silicate.
Salicylic Acid.
Benzoic Acid.
Formalin.
Preservaline.
Sodium Sulphite.
Freezene.

There may be a few other chemicals that might be added to the list but surely the above is enough. Most of us have preferences as to the manner in which we start for the other world and personally we object to the slow poison method, even if it promotes the wealth of the dealers in food products. Others may be equally sensitive and to all such we would say, as they do in the western mining camps when invited to drink, "Gentlemen, nominate your poison".

PLAIN TALKS ON BACTERIA AS APPLIED TO FARM PROBLEMS.

[By PROF. H. L. RUSSELL.]

Second Series No. XIX.

TOMATO AND POTATO WILT.

The relationships of plants are strikingly shown in the case of some bacterial diseases. The disease known as the potato and tomato wilt, illustrates this fact. Both of these plants are among the most common of our cultivated plants, and yet how few have ever noticed any resemblances between them, that could be taken for close relationship. Although the character of the product derived from them differs greatly, one being a tuber and the other a fruit, still if the blossoms of the two plants are closely compared, a striking resemblance is at once evident. The bacteria recognize this relationship, for they find in these two plants conditions that are favorable for the development of a common parasitic form. Other species of the same family are also susceptible. Among the cultivated forms, the egg plant acquires the disease, and among the wild species that are sometimes affected, is the "Jimson weed" and the "black night shade," both of which have an unsavory reputation, although they are members of the same family.

DISTRIBUTION OF THE DISEASE.

This disease has only recently been studied, and consequently its distribution is not thoroughly known, but already it is found abundantly in the southern states, where it has received the name of Southern Tomato Blight. The disease not infrequently is the cause of very severe losses. It is characterized, as its name implies, by a blighting or wilting of the foliage. Generally it begins on some of the younger branches, but quickly extends backward, often invading the whole plant.

An examination of the woody tissue of the stem shows that this tissue is particularly prone to the disease, the vessels often becoming completely plugged with a stinking, slimy growth. Where the potatoes are affected, the disease often runs down the stem, thus causing a rot of the tuber. The trouble in such cases can be readily recognized, as a cut section of the tuber will show a blackened ring of woody tissue near the edge of the potato.

MODE OF INFECTION.

There can be no doubt but that the cause of this disease is a parasitic micro-organism. It has been frequently found in affected tissues, and isolated from the same. When artifically introduced into a healthy plant, the disease makes rapid progress. A question of great practical importance is how the organism finds its way into the plant under natural conditions. The first point on which infection is usually noted is the tender, succulent stems. On potatoes, the germ is able to find its way into the plant, by means of the injuries caused by the common potato beetle. This insect distributes the organism by passing from infected to healthy plants, and vice versa. In all probability other insects also aid in the dissemination of the causal organism.

TREATMENT.

As the diseased plants contain enormous numbers of the specific bacteria, associated with the disease, it inevitably follows, that unless they are removed, the danger of spreading the trouble is greatly increased. Naturally, crop rotation is of considerable service in checking real troubles, as the germ only finds, in the potato family, suitable conditions for its rapid spread.

OTHER BACTERIAL DISEASES.

Several bacterial diseases have already been considered. These will suffice to indicate the general nature of this type of plant disease. Of course, in comparison with other plant diseases, caused by insects and fungus enemies, the bacterial maladies are of minor consequence, but with the close search which has been given to this subject, within the past few years, a not inconsiderable number of diseases have been, more or less, thoroughly worked out.

The wilt of cucumbers and melons belongs to this type of plant foes. Among the tree forms, there is the so-called olive knot, sometimes referred to as tuberculosis, on account of the knot-like excrescences, which are formed on the branches. Among the flowering plants, may be mentioned the disease of hyacinth bulbs and that of geranium or pelargonium cuttings.

The wide spread diversity of this group of plant enemies, emphasize the important fact that bacteria are, by no means, entire strangers to plant tissues. While they find, in animal cells, better conditions for development, still they are frequent enough in vegetable tissue to warrant a consideration of their activity.

Spraying has been of greatest service in combating many of the fungus maladies, but, naturally enough, such methods are of little avail in fighting an enemy that works its way into the inner plant tissues, beyond the reach of any spraying liquid. In the case of many of the fungus troubles, the cause of the disease is outside of the plant cells, frequently on the surface of the leaf. It is, therefore, possible to destroy the infective agent by the application of some disinfectant, which will kill the invading organism, but such a treatment, to be effective, should not injure, materially, the cells of the host plant.

Much can be done in repressing the ravages caused by these organisms, if their life history is thoroughly understood. If one knows how the germ is disseminated, how it finds its way into the host, much can be done to prevent such an occurrence. Restrictive measures should command much greater attention in these cases than they usually do, for with these maladies as with human, an ounce of prevention is worth a pound of cure.

Success In Dairy Work.

ED. HOARD'S DAIRYMAN:—Two years ago I commenced reading HOARD'S DAIRYMAN, at the same time I commenced dairying with three native cows. I read more, and purchased more cows.

I purchased a farm for $8,500 on time Jan. 1st, 1898. I built in February a 30x34 cow barn, 29 stalls floored and guttered in good shape, with feed alleys and walk ways, (2 stories) matched upper floor. I read and studied more from your journal each week, and then I purchased a 4-bottle Babcock tester, and gave $65. for a three month old registered and pedigreed bull calf. Went to Nashville and got 10 grades and thoroughbred Jerseys.

Later I put in dairy room 12x24 ft., 70 ft. deep well (tubular) tin pipes, galvanized force pump. I have read and studied all I could this year, and have added cream separator (Sharples machine) and have ordered 2-horse power (tread) and will churn, pump and separate by power.

Have the lumber on the ground for silo 24x18 ft. and will purchase shredder and fill same, this summer.

We sell whole milk at 4 cents per quart, cream at $1. per gallon, butter at 25 cents per pound, buttermilk and skim milk at 10 cents per gallon.

Out of 50 pounds of cream ripened, we only got 22 to 23 pounds of butter. Is this about right. At present we are milking 20 cows; make 300 to 500 pounds of butter per month and never have a pound 48 hours old. We print in 1 pound prints; wrap in parchment paper, then in veneer wrappers and pack in 56-pound shipping box with ice chamber and deliver every day. Churn three times per week.

Now that the DAIRYMAN has done this for me, it will do as much for others if they will subscribe and read it. I paid $5200.00 on the $8500.00 in 1898.

Now kindly point out my errors in the past. If the ideas were good, say so. If not, say so, and tell me if the turnout is about right. 50 pounds of cream to 22 to 23 pounds of butter. W. H. JOHNSON.

Mississippi Co., Ark.

No judgment can be formed as to the proper yield of butter from a given weight of cream, without a determination of the per cent of fat. Cream is so irregular in its composition, that from a given weight ten or twenty pounds of butter may be churned. Testing the buttermilk is the only way to determine if the yield of butter is what it should be.

It would be a work of supererogation to pretend to criticise our correspondent's work. The returns speak for themselves, and we would only call attention of the readers of the DAIRYMAN to the results that can be obtained in the dairy by the application of sound business principles and good judgment.

Dairy Work in the Maritime Provinces.

Luxuriant Pastures.—Fair Prices for Dairy Products.—The Chances for a Great Dairy Year.—Canadian Bacon on Top.—Increased Consumption of Choice Bacon.

ED. HOARD'S DAIRYMAN:—Quite a lot of rain fell in eastern Canada, in the past week. It looks as if the dearth of rain in the month of May is to be paid now with good interest. Rain fell on the 14th, again on the 15th, continuing all night. On the 16th, an intermittent rain fell all day. The following days were fine and warm as was also the 20th. On the 21st rain fell most of the forenoon, and to-day, the 22nd, it is misting rain.

As a result the pastures are generally thick and luxuriant, and the hay crop is looking up fairly good.

Milk is now abundant; probably as abundant in these provinces as it was this time, last year, and last year was a banner year for milk. The factories are all running. I do not know of a single factory that is not running this season, and this speaks well for the dairy industry.

As green food, such as peas and oats, corn, etc., was a superfluous quantity, last year, owing to the continued luxuriance of the pastures, I fear the usual heath of supplementary feed has not been sown this year. However, if so much rain continues to fall such feed, as last year, will not be needed.

The price of cheese is fairly good. Though few sales have yet been made, 8½c is about the present price. The Liverpool market is not as strong as this time last year, owing to

the large increase of exports over last year, at this date. The increase from Canada alone at this date is fully 100,000 boxes over the same period last year.

The increase of exports at Montreal alone is about 85,000 boxes, while the make in eastern United States has greatly exceeded that of last year. It looks therefore that many of the eastern creameries have been turned into cheese factories. Butter is steady at 17c. The increase of butter shipments have also largely increased over last year, though the market in Britain is reported lower. It looks, therefore, as if this year of 1899 is to be a phenomenal year in the history of Canadian dairying—and American also.

Bacon hogs are now selling in the principal Canadian market centers at $5 per cwt. for choice, and the outlook is for decidedly higher prices. This is quite in contrast to the American market when the top price, last week, was $3.95, which was at Chicago, —a margin in favor of the Canadian hog of $1 05. This is most remarkable. It is quite inexplicable to find hogs selling on either side of an imaginable line, a few hundred miles apart, as at Buffalo and Toronto, at a difference of $1.05. One should think that the time has come for the American hog to kick, or rather, squeal, to find himself at such a discount below his Canadian brother of the pig pen.

The high price of Canadian hogs is the more unusual when we come to consider the phenomenal increase of Canadian hog products to the English markets during the year just past. A few of our friends across the line have been saying "What's the use for us to begin catering to the English market. There is a market there for only a few thousand aristocratic consumers and will soon be glutted."

Well, evidently there are more than "a few thousand aristocratic consumers" of fine Wiltshire bacon in Great Britian, for somebody in that great discriminating market consumed over $5,000,000 worth of Canadian bacon in the last twelve months. The exports of bacon from Canada has fully doubled and yet the price of the product is advancing, and the outlook just now is that the market for Canadian bacon will still further advance.

The market is strong with an upward tendency and the chances are that before long the price for choice bacon hogs will run to $6 per cwt.

The history of choice bacon is very much like that of creamery butter and full cream cheese. In the early history of the creameries, the dictum went round that there were but a few thousand of the upper ten in Britian and this country who would consume choice creamery butter, the great majority would continue to use the cheaper dairy butter, but the outcome was, and is, that all classes, including the dollar a day laborer, buy creamery butter instead of the home dairy make. I believe a very small percentage of the people purchase "oleo" knowingly. Now this is, and will still further be, the case with choice bacon. A largely increased class of consumers, both in Britian and this country buy choice bacon rather than the pickeled hunk of fat, or the very fat, ill-flavored, corn fed bacon. Bacon and butter is certainly the new alliterative for our farmers to bank on. J. A. M.

Hermanville, P. E. I.

The Use of Cyclone Churns.

[Press Bulletin.]

From time to time there has been introduced into the dairy community unique forms of churns. Hundreds of varieties have been patented, and the farming public, as a result, has suffered from the introduction of many of these ex-perimental, undesirable churns.

Under ordinary conditions of churning, modern dairy authorities generally agree that churns should be free of all forms of inside paddles or dashers. This is because where different lots of cream are churned together at one time, they are often unevenly ripened, and butter comes from some of the cream sooner than from the other. The butter which comes first is more or less injured when struck and rubbed by the paddle or dasher, so that butter of inferior grain or quality is produced.

During the past few years, several forms of churns have been introduced in the United States that are advertised to bring the butter "in a minute and a half," and remarkable results are promised the farmer who uses one of them. These churns are of the shape of an ice cream freezer pail, and contain a set of arms or dashers near the bottom, that are revolved at great speed by a geared arrangement at the top of churn, operated by a crank handle.

In April and May tests were made of one of these churns at the Indiana Experiment Station. The churn was small of capacity, so but eight pounds or one gallon of cream was used in each trial. The trials were made under as favorable conditions as possible, to produce good butter. The cream was placed in the churn at a low temperature, ranging in the different trials from 53° to 56°. At the former temperature the butter came in seven minutes; at the latter, in 15 minutes. At 53° a yield of three pounds and one ounce of salted worked butter was secured; at 56° two pounds and twelve ounces was obtained. The amount of butter fat left in the buttermilk showed that the butter had been quite satisfactorily separated from the cream.

The removal of the butter from this churn, however, was the objectionable feature. If the butter was warmed up to 62°, a very common churning temperature on our farms, it could not be nicely removed from the churn. The paddles beat it considerably, and after giving such careful washings of the butter as seemed desirable, the contents of the churn in each case smeared in an objectionable manner. In winter, in a cold room, the work of the paddles would still be undesirable.

This type of churn, for the reason given, is not to be recommended over the standard barrel of box churns, free of all inside devices. The revolution of a simple barrel or box churn, containing no paddles, in a cool room with cream at 54° to 56° temperature, should give the most satisfactory results to the dairy farmer. C. S. PLUMB, Director.

Iodide Cure for Milk Fever.—When is a Heifer at Her Best?—Effect of Lactation on Fat Content.

ED. HOARD'S DAIRYMAN:—Your readers will be interested in a trial of the iodide of potassium treatment of a case of milk fever. She was a fine Jersey with calf two days old. She was down and unable to hold up her head, and would not notice anything. Having recently noticed the potassium iodide treatment recommended in the DAIRYMAN of May 12th, we concluded to try it. We boiled one quart of water and when cooled to "milk warm," dissolved two and a half drachms of iodide of potassium in it, and introduced 8 ounces of this solution in each teat by means of a milk tube attached to a fountain syringe. This was done about 9 a. m., and at 2 p. m. she was holding her head up and shaking flies off of her ears. We then gave her two pounds of Epsom salts and two ounces of aromatic spirits of ammonia, and removed the placenta, which had not passed. At 6 p. m. she was up eating grass; got well right away. We think this a wonderful treatment for milk fever.

1. We notice that Prof. W. A. Henry, in U. S. Reports, recommends 22 lbs. of dry matter containing 4 lbs. protein, 13 lbs. carbohydrates, and 2 lbs. fat as a ration for calf two or three months old. Is that not more than they can consume?

2. What is the feeding analysis of Bermuda grass?

3. Is there a difference in the percentage of butter fat in a cow's milk with her first calf and her third or fourth calf?

4. What effect does period of lactation from birth of calf have on percentage of fat?

Newton Co., Ga. C. C. BROOKS.

Decidedly a misprint, Prof. Henry never advocated such a ration.

We do not know of any digestion experiments having been made with Bermuda grass and consequently cannot give its digestible nutrients. The analysis shows as follows: Protein 9.16, fat 1.38, carbohydrates 46.06. The analyses show wide variations in the composition, according to the time of cutting, ranging from three to eleven per cent in protein, according to age, etc.

Sometimes a heifer will not do her best till her third or fourth calf, and again she does her best at the first coming in. There seems to be no certain rule.

With but few exceptions, there is a regular and constant decrease in the amount of milk produced and in the size of the fat globules. At the same time there is an increase in the per cent of fat present, but a decrease in the total amount of fat produced.

Jersey Breeders' Meeting.

ED. HOARD'S DAIRYMAN:—There will be a summer meeting of the Western New York Jersey Cattle Breeders' Association held at the "Cold Spring Farm" of the Vice President, Hon. M. H. Olin, Perry, N. Y., on Thursday, June 29, 1899.

All persons interested in Jersey cattle, whether members of the Association or not, are cordially invited.

Please notify Mr. Olin, or the Secretary at as early a date as possible of your intention of being present.

GEO. E PEER, President. L. D. ELY, Secretary.

Got Rich at Dairying.

In the Eighteenth District Institute, and Fayette County Farmers' Institute at Vandalia, Illinois, L A. Spies, of St. Jacobs, said that he had made enough in dairying to retire from business, and live comfortably the rest of his days, and that any intelligent farmer could do the same thing. He attributed his success to careful selection and breeding of his cows, generous feeding, and marketing of his milk in the best possible condition. He utilizes all his corn crop, either as green feed direct from the field or through the silo. He recommended those who are about to begin dairying, to visit some successful dairyman before investing, either in cows or appliances.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

GLOSSARY.

The terms used in this department of HOARD'S DAIRYMAN have the following significance:

RATION.—The total allowance of feed for twenty-four hours.

DIGESTIBLE NUTRIENTS.—That portion of the organic matter which can be digested by the animal and does not pass off through the bowels as excrement.

PROTEIN.—That part of the digestible nutrients which goes to the formation of lean meat, ligaments, hair, horns and the casein (or curd) of milk. It is generally believed, also, that protein may be, and many times is, converted into the fat found in milk. The basis of protein is nitrogen, hence the protein elements are frequently termed the *nitrogenous* parts of the food. They are also called *albuminoids*.

CARBOHYDRATES.—That part of the digestible nutrients which is the primary source of sustaining animal heat and furnishing the power for keeping the animal mechanism in operation. They are composed of the woody fibre of the plant and grain, and the starch, sugar, gums, etc., and in the published tables of chemical analyses are usually subdivided into the terms *crude fibre*, which is the least digestible portion of feeding stuffs and *nitrogen free-extract*, so-called because it does not contain any nitrogen.

ETHER EXTRACT.—That portion of the digestible nutrients which may be dissolved out of the food stuffs by ether. It is frequently called *crude fat*. Whether fat is actually digested and thus passed on into the circulatory system in a changed form or whether it is simply separated from the other elements and always maintains its identity is an unsettled problem. It can be used by the animal for maintaining the body temperature, and for this purpose is from 2.2 to 2.5 times more efficacious than the carbohydrates. It is maintained, by some, that the fat in the milk comes, largely, from the crude fat in the food, but it has been demonstrated that it is not absolutely necessary, for this purpose.

FEEDING STANDARDS FOR MILCH COWS.

Dry matter.	DIGESTIBLE NUTRIENTS		
	Protein	*Carbohydrates.*	*Ether extract.*
lbs.	lbs.	lbs.	lbs.
23 to 28	2.0 to 2.5	12. to 15.0	0.5 to 0.8

MILK NOT CHURNING.

Will you please tell me the remedy that will prevent milk from wheying? We have tried salt in the food of the cows, but it does not seem to avail. When the milk is churned it seems nearly all to go to whey, leaving a small quantity of grainy, white substance, like curd. J. S. R.

Wesson, Miss.

Under no conditions can the best results be obtained when whole milk is churned. No matter what precautions are taken, the fat can not be churned from whole milk without leaving a large per cent of the butter fat behind. Separation and churning the cream is the only remedy. In the above case, fermentation has been allowed to go too far, and the milk has "wheyed off."

Cream or milk that has "wheyed off" through fermentation, will not churn well; in some cases, not at all. Food or salt will have no effect where the cause is purely bacterial.

APPLYING FLY MIXTURES.

In your issue of June 2nd, you mention two fly preventives. You state that 1½ pint will go over 12 cows and last 5 to 6 days. Will you kindly tell me how to apply mixture, as I find the greatest expense comes from the wasting of a good deal of the mixture. R. H. W.

Quincy, Ill.

It depends on the consistency of the preparation used. If it is quite fluid, a cloth can be wet in the solution and rubbed lightly over the animal. If kerosene or kerosene emulsion is used, a spray pump does excellent work. If of thick or sticky consistency, it may be necessary to use a short stiff brush.

CORN FOR THE SILO.

Do you recommend mammoth Virginia variety of corn for the silo, and is the corn with a heavy foliage and less ears as good for silo as regular field corn?

Am getting lots of good dairy information from your paper; would not do without it. Have been feeding your balanced ration for the last year. O. K. W.

Three Oaks, Mich.

You are probably too far north for the mammoth southern corns to mature sufficiently for the silo. The large southern corn grown in the north, though seemingly giving a large yield of nutrients, may contain less than ten per cent of dry matter. A long growing, late maturing kind is best adapted; one that will contain a maximum of dry matter when put in the silo. Consult the growers in your locality, and use the corn that gives the largest yield of corn with glazed ears.

CREAM, BUTTER FAT AND BUTTER.

The farmers in this neighborhood are giving their cream to the creamery where it is manufactured into butter, at a cost of three cents per pound, and they, the creamery-men, do the hauling. Now then, what I want to get at is this. How many pounds of butter should there be in 881 pounds of cream testing 32%, and adding 16% for overrun?

California. J. B. C.

The amount of butter fat contained in the cream, at the figures given, would be 282.9 pounds. The overrun will depend on the conditions under which the ripening and churning of the cream are carried out. It may be from 16 to 20 per cent. Taking it at 16%, as above requested, it would amount to 328 28 pounds of butter. The figuring is as follows:

Multiply the weight of cream (881 pounds) by the per cent of fat (32%) and the result will be the weight of fat present. Multiply this by the per cent of overrun (16%) and add the result to the amount of fat found. The product will be the weight of butter that can be made.

FISH OIL.—CRIMSON CLOVER.

In a recent issue you give a receipt for keeping flies from cattle. Will you please state what you mean by fish oil, as our druggists claim there are several kinds. Also, how much crimson clover to cultivate in with corn? E. H. M.

Owego, N. Y.

When fish oil is spoken of without specification it means Menhaden oil, as that is the cheapest that can be obtained. Other oils can be used, but they cost more.

At the last cultivation of the corn, sow on the fresh earth, eight to ten quarts of crimson clover seed per acre. If to be used as a fertilizer, let it remain after the corn is removed, as long as possible, and then turn under just before the ground freezes.

In Long Island, New York, the authorities are proceeding in rather an unusual way to enforce the oleomargarine law They are suing out injunctions against grocerymen to enjoin them from disposing of the oleomargarine as butter.

How many miles of sunburnt pasture do your cows travel over, this summer, to get a full meal? Consult the milk yield and you will find that long tramps after food and a small milk yield go together. A summer silo would prevent this loss and increase the returns to a wonderful degree.

What shall it profit a man if he saves one dollar by using a scrub bull and loses ten dollars in the value of the calf? The dollar saved is held so close to the eye that it hides the future value of the calf as well as the yearly profit from a good cow. The dollar saved by using a scrub bull is a lost dollar in the end, and many more must follow it because of poor and unprofitable animals, produced by a degenerate sire.

Dirty, rusty cans will reduce the price of butter quicker than a poor butter maker. A poor butter maker can make good butter if the milk is good, but no one can make extras with milk from cans that are rusty, unwashed, and unkempt. That thin film of rancid grease and casein which adheres so firmly to the inside of a dirty can, will spoil the best milk from the best cow in the world, and as the milk is, so will the butter be, and the price will follow it in its degradation.

How much of the sickness of the dairy cow is caused by dark, unhealthy stables, is an interesting question, but it is certain that a dark, gloomy, damp stable is an excellent place for the propagation of all kinds of bacteria. It requires no argument to prove that the resisting power of an animal against contagious diseases, is much reduced by damp, dark stables and as it is a well known fact that sunlight is a deadly foe to bacteria, it naturally follows that an animal has a double chance of resisting sickness if its surroundings are light and dry. How much poor and unhealthy surroundings are responsible for milk fever, garget, abortion and like ills, cannot be exactly determined, but there is no doubt that darkness and dampness are strong allies in their continuance.

Let light and air into the stables both for the good of the cow and your pocket-book.

DEATH OF J. G. CHERRY.

It is with feelings of deep regret that we announce the death of that veteran manufacturer of dairy implements, Mr. J. G. Cherry, of Cedar Rapids, Iowa, which occurred on the 18th inst.

The dairymen of the United States owe a debt of gratitude to Mr. Cherry for his early and persistent effort to give them the best possible implements that the wisest thought could devise. He was an enthusiast on all subjects connected with dairy progress, and a firm and devoted friend to this interest.

DIFFERENCE OF BRAINS IN DAIRY WORK.

Prof. E. H. Farrington, of the Wisconsin Dairy School, makes a good point in illustration of the claim so long maintained by Hoard's Dairyman, that this business of dairying calls for intelligent brain work. He sends to the *Farmers Review* a statement of two students who have attended the Wisconsin Dairy School. One was a brainy fellow who realized what study meant, and was determined to make the largest use possible, of all the knowledge within his reach, while at the school. He writes Prof. Farrington that since his return to his creamery, he is clearing $20 a day by an idea he picked up at the Dairy School.

The other student writes for information in cream testing, and confesses in his letter that although he took the laboratory work, he did not give much attention to it, for, as he says: "I never expected to have any use for such a thing."

To all this Prof. Farrington makes comment as follows:

Among the 120 dairy students which we have each winter there are always some who need to be convinced that whatever they can learn about milk will sometime be useful to them in any branch of dairying. Butter makers will be helped by learning something about cheese making and vice versa. No man can learn too much, but some fail to realize this until too late.

The particular point about cream testing that bothered this young man may cause trouble for others. He had tested milk for years, but when his patrons began to get hand separators and send cream to the factory, he found that it did not always test so easily as milk. Sometimes the fat was not clear in the test bottle neck and a muddy looking deposit was often mixed with it. This difficulty can generally be overcome by allowing the mixture of cream and acid to stand in the test bottles for ten minutes before they are whirled in the centrifuge. Cream contains so much more fat than milk that it takes a longer time for the acid to complete the solvent action that clears the fat, than is the case with milk. Another sure way of clearing the fat in a cream test is to allow the cream test bottles to stand for an hour or so after the test has been completed, and until the fat cools and solidifies. If the test bottles are then placed in hot water and the fat melted again it will be clearer than it was before the crystallizing and remelting.

It is the work of good brains to appreciate the value of good knowledge. The first student had that appreciation. He made $20 a day by it. The second did not have it, and he let his mind starve with a full table of knowledge before him.

What is true here is just as true on the dairy farm. We see it proven every day and everywhere. One farmer sees the value of good, well bred dairy cattle. He keeps a registered bull and saves and picks up every nice grade heifer calf he can find. Then he advertises his stock.

This is what F. W. Tratt, of Whitewater, Wis., does. Last week he sold to Mr. Thomas, of Eau Claire, Wis., for the Moore Farm at Stanley, Wis., twenty-eight of these young grade heifers for nearly $700. These cattle were all grade Guernseys. Mr. Thomas also bought several more full blood and grade Guernseys from other farmers in this vicinity.

What brought him here for this purchase was the fact that a few farmers had exercised intelligence enough to breed good dairy cattle of one breed. They had selected one breed and stuck to them. That was the work of good brains. The more of such farmers in any community that will do this good brain work, the more will that community become a center for that particular kind of cattle. Then, if they have the good business sense to make these facts known, and advertise their cattle, buyers who want that particular breed will flock there to get them.

Out of a radius of fifteen miles, including Ft. Atkinson, Whitewater and Lake Mills, there have gone out this spring, several car loads of these dairy bred cattle, to distant points. One community will breed Holsteins, another Jerseys, and another Guernseys. Every grade heifer of either is carefully nurtured and fed, for she is sure to be wanted at a handsome price.

In the same territory are other farmers who don't believe in using that sort of brains. They use all sorts of bulls, with no regard to improvement in a straight breed line. Buyers who want well bred heifers, do not visit their farms.

It is the old, old story of using brains on the farm. There is money in it. There must also be a good deal more satisfaction in being that kind of a farmer.

It is somewhat difficult to get farmers to see that there is a great deal more profit to them in going together, say a dozen or more farmers, in the breeding of one kind of cattle. It becomes an object, then, to buyers from a distance, wanting that particular breed, to visit that community.

There is a big difference in profits between up-to-date, brainy farming, and scrub farming with scrub cattle.

A WELL MANAGED CO-OPERATIVE CREAMERY.

At a recent meeting of the Riverside co-operative creamery near Rockford, Ill., a showing was made of the comparative amount received for butter fat for the year ending April 30, as compared with the twelve months previous. The increased amount was nearly three and one half cents per pound. Concerning the way the creamery is managed the *Gazette* of Rockford says:

It is quite frequently the case that co-operative creamery companies have much jangling and lack of harmony; sometimes the dissatisfaction going to such an extent as to result in dissolution. But the Riverside is a notable exception. There may be differences of opinion on various matters, but all seem perfectly willing to submit to the majority.

Here we have one secret of the increased profits of the past year—the patrons pulled together. Still greater profits will come if they will make a special study of dairying, which means the raising of dairy crops, breeding and feeding dairy cattle with dairy intelligence, the construction of dairy stables, the manufacture of dairy products and their final sale. All of the foregoing, except the last two, are live, patent questions to every patron of a creamery or cheese factory. The reason why there is such a wide difference in the profits of patrons in the same creamery, is because one man studies the business and the other does not.

A Good Butter Record.

Ed. Hoard's Dairyman:—We are milking five grade Jersey cows, two are heifers with first calf, and one of them has not been fresh since last September, one has had her second calf, and the other two are older. The five give 98 pounds of milk daily, and from that we make 45 pounds of butter per week.

We use a hand separator, and have churned 14½ pounds of butter from three gallons of cream. We pack the butter in tubs and ship to the city market at creamery prices.

As we have just started on this plan but a short time ago, I would like to know how this compares with others, so that I may know how my cows rank with other common cows, as butter cows.

Could you suggest a better plan in regard to marketing the butter, that we may realize more from it?

I am one of your five months subscribers, and like your paper very much, as I get many good ideas from it. J. F. B.

Hamersville, Ohio.

Forty-five pounds of butter weekly from five cows is a most excellent performance, and our correspondent is to be congratulated on the quality of his herd. At the same time it would be interesting to know what individual animals are doing, and the use of a Babcock test would give some valuable data, when used on even the best herd.

As regards marketing the butter, with such a herd there should be an excellent chance to find private customers for all the butter the herd can produce.

It would require more labor and care, but the returns would be more remunerative than sending to a commission man.

"To Err is Human."

But to err all the time is criminal or idiotic. Don't continue the mistake of neglecting your blood. When impurities manifest themselves in eruptions or when disordered conditions of stomach, kidneys, liver or bowels appear, take Hood's Sarsaparilla. It will make pure, live blood, and put you in good health.

Hood's Sarsaparilla
Never Disappoints

Flax Seed Meal for Calves.

Ed. Hoard's Dairyman:—Kindly inform me where I can get the ground flax meal for calves. I do not want oil meal, but prefer the whole flax seed meal.

Burdette, S. D. C. W. Simons.

Ground flax seed can be procured at almost any drug store, although a somewhat high price is usually charged for it at such stores. We have always thought it paid a handsome profit to buy and use it. In addition, the calves should have access every day to unground oats, after four weeks of age. Commence with the flax seed meal with the first feeding of skim milk, turning on boiling water before adding it to the milk. Do not use more than a tablespoonful a day at first, or until the calves begin to chew the cud, which is usually in four to six weeks after birth. Watch well the the voidings and if too great looseness occurs, let up on the flax meal. Some persons use the whole flax seed well boiled.

Texas Fever and Ticks.

Ed. Hoard's Dairyman:—I notice in the Dairyman of May 5, Prof. Russell attributes Texas fever to ticks. Now I do not believe that a bushel of ticks put upon one animal would cause it to have the Texas fever, and I am quite sure that if you brought cows from the north and stabled them with your native cattle that were kept in stable and were perfectly free from ticks, the cattle brought in would soon take the fever and die.

Sixteen years ago last January I bought four two-year-olds and two calves, Holsteins. I put them in a field where a heavy coat of grass had just been burnt off, which of course destroyed the ticks, and in about two weeks the four two-year-olds took the fever, and three of them died. I do not think they had a tick on them.

Last June to further test the matter, and at the suggestion of one who believed in the tick theory, I bred and sent to my farm in Illinois about 5,000 young ticks and had them put upon a two-year-old steer, and there was not the least possible symptoms of the fever; but I propose to send more this season as a further test.

I should like to have some one ship a few head south and stable with natives, when they were free from ticks, and see the result. Who dare try it? N. H. M.

Manville, Fla.

More Inquiries About the Vetches.

Ed. Hoard's Dairyman:—I wish to thank the friends from Oregon and New York, who so kindly answered my query in regard to vetches. Since asking the question, I find a patch grown along a fence row, from

Not a Preservative

but a preventive. If you would have your milk keep sweet longer and be free from all objectionable odors, use a CHAMPION Milk Cooler-Aerator. It does its work perfectly and it's use does'nt violate any law—it doesn't need to be used on the sly. Our book "Milk" is free.

CHAMPION MILK COOLER CO.,
67 Main Street, - Cortland, N. Y.

the seed sown a year ago last spring. As I am using the soiling system exclusively, I am very anxious to use every plant available in that line, and would be very thankful if these friends (especially in the climatic conditions of New York) would state about how much vetch seed, and how much rye per acre is used when sown together, for best results. Whether sown and covered at same or different times; and if winter vetch is not best on rich black soil. J. P. D.

Fowler, Ind.

A Florida Experience.

ED HOARD'S DAIRYMAN:—I have a small herd of high grade Jerseys, but I am not satisfied. I have, this past winter, brought in a very fine young bull and heifer calves from Ohio. I want the best herd of Jerseys in the state, and I can see no reason why I should not have them.

Before coming to Florida, I had a fine herd of Holsteins. I do not think they are as well adapted to this state as the Jerseys.

We make butter, and have no trouble about its keeping, though we do not keep it over two weeks. Our butter stands up much better in warm weather than the northern butter. If you use northern butter in warm weather and no ice, you must handle it with a spoon. Not so with our make.

No use of my saying complimentary things about the DAIRYMAN, I could not do the subject justice. N. H. M.

Mannville, Fla.

Hood Farm Butter Test.

ED HOARD'S DAIRYMAN:—We report, this week, butter test of a daughter of Tormentor 3533, Imp., and Addie P., 41428, a full sister of Lily Martin, of World's Fair fame. Tormentor's Lass 59832, dropped Dec. 28, 1888, dropped her last calf by Tormentor, Jan. 1, 1899. This gives the calf 50 per cent of the blood of imported Tormentor. For the week ending Feb. 5, she gave 281 lbs. 15 oz. of milk that churned 17 lbs. 14½ oz. butter. For the two weeks ending Feb. 9th, she gave 565 lbs. 1 oz milk that churned 35 lbs. 8¾ oz. butter. Her daily ration was 4½ lbs. bran, 4½ lbs. corn meal, 2½ lbs. ground oats, 1 lb. oil meal, 1 lb. cotton seed meal, silage and hay *ad libitum*.

Tormentor Lass is a cow of great capacity and very fine finish. She has given in the five months since dropping her last calf, 5,622 lbs. 10 oz. milk and is milking at the present time 33 to 35 lbs. per day, thus showing the most valuable characteristic of a dairy cow—persistency as a milker. She has been bred to Torono, a son of Sophie's Tormentor, in use at Hood Farm. HOOD FARM.

Lowell, Mass.

From a Pennsylvania Dairy.

ED. HOARD'S DAIRYMAN:—We take great pleasure in reading the report of our brother dairymen, and herewith add our mite. During the month of May our herd consisted of three two-year-old heifers, four cows due to calve in September, and nine cows that dropped their calves before the middle of April. From 11,727¾ pounds of the milk that they gave during the month, we made 743¼ pounds of butter. Nine of the herd are daughters of Maud's Eurota Pogis No. 34864, whose dam Maud of Maple View No. 39511 made a record of 23 pounds, 10½ ounces of butter for Mrs. Kate M. Busick, of Wabash, Indiana. During the week ending May 25th one of the herd, Theresa Leonard No 104625, gave 301¾ pounds of milk from which we made 17 pounds, 7½ ounces of butter, salted one ounce to the pound.

AUSTIN LEONARD & SON.

Bradford Co., Pa.

Kerosene for Flies.

ED. HOARD'S DAIRYMAN:—I find a spray pump for spraying the cows with pure kerosene, to kill the horn fly, is an excellent remedy. The fly turns on his back at once. A pint of oil sprays thirty cows several days. I have begun early with the horn fly, so as to kill off the first generation.

My three-old bull got noisy and cross, and I hung a pound or two of an old pully on his nose for a jewel. It works admirably.

I am a gallon of cream short to-night, because of the severe rain of last night. There is more than one way to skim milk.

Viroqua, Wis. C. V. PORTER.

Power for Silo Cutter.

ED. HOARD'S DAIRYMAN:—Tell Buff Jersey his eight horse-power is plenty heavy for a 16-inch Ross cutter. I filled my first silo with a 14-inch Ross cutter, 20 feet carrier and a two-horse tread power, with only 1,100-pound horses, but could cut only 10 tons per day.

I now run a 16-inch cutter with traction engine. I have 50-foot carrier and think the engine could pull two more just like it. The engine is probably 14-horse power.

Our engine is 75 feet from cutter; use same belt as in threshing, but use a jack near the cutter to carry the weight of heavy belt. Then use a short one from jack to cutter. P. CLAWSON.

DAIRY PAPERS.

J. H. Monrad, the veteran dairy writer, has the following to say in the *Farmers' Review*, concerning his opinion of the value of dairy reading to the man who is trying to make money out of cows:

"Years ago, when the dairymen were allowed only one page, I felt kindly toward the *Farmers' Review*, simply because I saw good reports of the various dairy meetings, and found that the editor attended these and took stenographic notes. How much more should the dairyman appreciate the two pages, which gives them their true importance among the farmer students. Yet it seems to me that the subscribers do not fully appreciate the value of the concession, as they do not write and tell their fellow workers what they are doing, their success, their failure (both equally valuable) or criticise what they read. I sincerely hope that any and all readers who milk even two or three cows will make themselves at home in this department and co-operate to make it still more useful. No question is too trifling, and large amounts may be saved by digesting the information given.

"As an example, let me mention the editorial note where the manufacturers of cans for raising cream by dilution are scored for using the word 'separator'. It is simply an attempt to get a high price for a cheap can with a faucet by conveying to the minds of the unwary the idea that it is a machine like the centrifugal separator, the cheapest of which is $65, and that they can sell one for $10."

A BUSINESS OF FRAUD AND BRIBERY.

Mr. James Terry, the local representative of the Pensylvania Dairy and Food Commission at Pittsburg, in a communication to the Commercial Gazette of that city, says:

"There has been more corruption, deception and bribery in connection with the sale of oleomargarine, and the efforts to restrict its sale in conformity with law, than with any other article manufactured for food consumption. * * * *

If a man pays the top price for creamery butter and receives oleo., and this has been the rule, not the exception—the transaction is a swindle. The dealer who practices the deception should be exposed and punished.

The new Pennsylvania law provides that persons selling oleomargarine colored to resemble butter shall on conviction be subject to a fine of not less than $100 nor more than $500, or imprisonment in the county jail for not less than ten days nor more than sixty.

Mr. James observes:

It is well known that manufacturers here, in order to induce dealers to sell oleomargarine in defiance of the state law, offered to defend any case brought against them and to pay any fines that might be imposed. It appears that the similar promises are being made to the dealers in Pennsylvania. "They may pay their fines," said Mr. Terry, "but they will not go to jail for their customers, and could not if they would."

"Dual-Purpose" Fruit.

The writer of this attended a farmers' institute at St Francis, Minn., a few days ago, and he was greatly surprised to learn that of the half dozen creameries built in that section a few years ago, only one was running, and upon inquiry as to the cause, it was found to be chiefly due to the influence of the dual purpose cow advocates. Farmers were easily led astray upon this subject, and many of the dairy bred cows were replaced by heavier ones. The result was such a shrinkage in milk that the creameries had not enough to make it profitable and so they closed down. Farmers who take the advice of men who know nothing about dairying, and care little for the development of the industry, but who are chiefly interested in seeing a goodly number of beef steers raised for the steer feeders and traffickers, will in time learn to their sorrow that the advice of such men cannot be profitably followed. If creamery patrons have any regard for their future welfare they will turn a deaf ear to the fine-spun theories of those who have never had any experience in the business, and that are in direct conflict with the results obtained by long and careful investigation at experiment stations, and in multitudes of first-class dairies. —*Farm Stock and Home.*

D. F. Sexton, of Snohomish, Wash., has a dairy of 21 Jersey grade cows, 11 of which are heifers. The production of those cows and heifers, last year, was an average of 305 lbs. of butter—another proof that it is not the location, but the men, that makes the real difference in the production and profit of this business. The first thing for every dairyman to strive for, is to be the right kind of a man with the right kind of ideas, and all things else shall be added.—*Hoard's Dairyman.*

Yes, but your bright readers can see for themselves that neither the men nor the location had as much to do with it as the influence expressed in that little word following 21. They doubtless have the "right kind of ideas," but if the word "Jerseys" had been substituted for "ideas," your last sentence would have been nearer the "thing" and nearer your inmost convictions —*Jersey Bulletin.*

Is that so? Well, we know of a number of men who have made a most lamentable failure with Jersey cows. "In the bright lexicon of your youth" is there any place for brains and good management or will the cow, if she is a Jersey, do it all?

Persistent Milking Wins.

Last season when the price for calves went skyward, many farmers who had patronized the creamery and raised the calves on skim milk, thought they could see more money and less bother in letting the calves suck the cows. The indications are that this year calves will not be worth as much money, and as the cattle stock of the country increases to the normal, calves will further decrease in value. These farmers who stopped milking and turned in the calves will then see the mistake they made. They will find that their cows are not nearly as good milkers as they were before, and it will take them several years to build up an efficient dairy herd again.

If there is any one thing about dairying that has been thoroughly and completely demonstrated, it is that milking makes milkers. The best cow in the world can be ruined as a milker in a comparatively short time by simply letting the calf suck her, or by carelessness in milking. The poorest cow can be improved by continued and persistent milking. The man who has ten or twelve, or more cows, and milks them year in and year out, keeps right at it and practices improved methods of feeding, will get ahead right along. It don't pay to milk the cows one year and let the calves suck the next—*Creamery Gazette.*

FIFTY YEARS OLD

Why let your neighbors know it?

And why give them a chance to guess you are even five or ten years more?

Better give them good reasons for guessing the other way. It is very easy; for nothing tells of age so quickly as gray hair.

Ayer's Hair Vigor

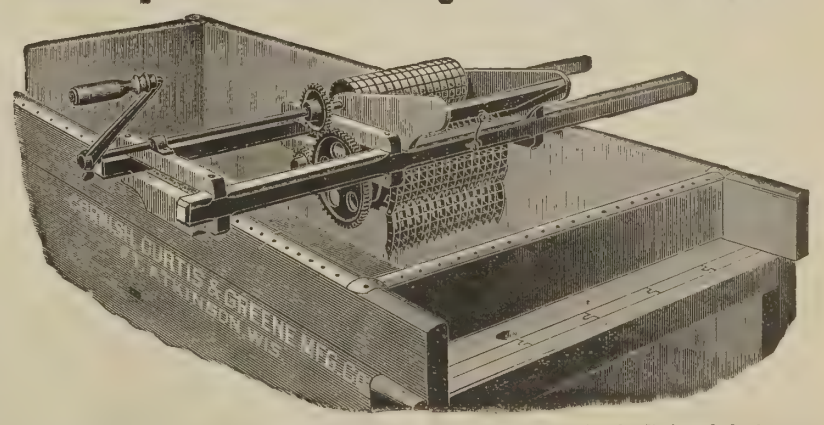
is a youth-renewer.

It hides the age under a luxuriant growth of hair the color of youth.

It never fails to restore color to gray hair. It will stop the hair from coming out also.

It feeds the hair bulbs. Thin hair becomes thick hair, and short hair becomes long hair.

It cleanses the scalp; removes all dandruff, and prevents its formation.



We have a book on the Hair which we will gladly send you.

If you do not obtain all the benefits you expected from the use of the Vigor, write the doctor about it. Probably there is some difficulty with your general system which may be easily removed. Address,

Dr. J. C. Ayer, Lowell, Mass.

PIGS Eligible to REGISTRY, and First Class Stock, at Reduced Prices. **Chester White, Berkshire, Poland-China and J. Reds. Thuroughbred and Grade Guernseys. Also Poultry. W. B. HARVEY, West Grove, Pa**

Kasper Rotary Curd Mill.

The demand for a large capacity curd mill for cutting curd into cubes has induced the inventor to bring out the Kasper Mill. In construction the mill consists of a rotary cylinder made of knives in the form of cubes. Against these knives a wooden roll revolves with indentations to fit the knives of the cylinder; the curd being fed into the hopper is forced through the openings in the cylinder by the wooden roll. The cylinder is made in three sections hung on hinges, and, as it revolves, each section as it comes to the lower part of the cylinder, opens and allows the curd to drop into the vat, the section closing again as the cylinder revolves.

It is estimated that the curd from 7,000 lbs. of milk can be cut in from 7 to 10 minutes. The mill operates easily, being light running and adjustable to either hand or belt power. Simplicity of construction, durability and ease of cleaning are some of its principal features. All parts being galvanized or tinned prevents rusting. Weight of the machine complete is about 38 pounds. List price, **$25.00.**

Seasonable Notes from Michigan.

Clean Water for the Cows.—Feed on Dry Pasture.—Cleaning Milk Utensils.—Soap.

ED. HOARD'S DAIRYMAN:—There are a number of things which ought to be impressed upon the minds of those having the care of cows and milk during the hot months of summer. No one can hope to succeed in securing a first-class article of milk, or to make fine butter, and allow such deplorable conditions to exist, as are sometimes found.

When cold weather comes, attention needs to be directed along the line of proper stabling, ventilation, the food and water supply, as regards the out of door work, while inside we have the difficulties attending creaming the milk in zero weaher, ripening the cream, churning, etc., where everytning must be closely and carefully watched, to see that a proper temperature is maintained.

In summer it does not seem that one's vigilance can be one particle abated. There are special difficulties peculiar to each season. Just now, on a good many farms, the cows are not supplied with plenty of good, pure water. The animals are allowed to drink from way side pools, veritable mud holes in some instances, and how can pure milk be expected under such conditions.

Only yesterday, while driving along the road just at chore time, I met a man driving his cows home from pasture. As I approached, he stopped to allow them to drink from a pool of stagnant, muddy water at the road side, actually thick and yellow with dirt.

Good well or spring water is best for stock of this kind. On a good many farms, wind mills are erected, which keep a supply of fresh water always at hand, and it is preferable that these are so located that the animals may drink at any time, not merely at morning and night.

An outlet to a tile drain, may often be utilized so as to furnish an excellent watering place. Make a trough and set at the outlet, usually, on a side hill where the stock can get at it. Arrange the overflow properly, and have the trough so placed that cattle cannot get in with the feet.

Running water is sometimes fouled by cattle standing in it to get away from the flies. In this case it soon clears itself again, and is not to be compared with the roadside pool, while, at the same time, leaving considerable to be desired by way of cleanliness.

The fly nuisance causes a loss of no mean dimensions, yet it is one hard to successfully combat. We know of nothing better than "Shoo-fly," or similar preparations, which require to be applied repeatedly. The labor involved in this is not, however, to be compared to the loss entailed, when nothing is done to prevent their ravages.

At least one feed a day of corn fodder, peas and oats, or some other supplemental food should be given milch cows when pastures become dry, during July and August. Anyone who appreciates the fact, that something cannot be made from nothing, will understand how necessary it is to supply a cow with all she wants to eat. When pastures are bare and flies troublesome, she is much better off in a darkened stable all day, where she has plenty to eat, than wearily plodding over the ground in the vain search for it, while flies make her life miserable.

Indoors, great care is necessary to keep everything sweet and clean.

All milk utensils should be washed as soon as empty and not allowed to stand. The milk adhering quickly dries upon the surface rendering its removal more difficult. Pouring hot water over milk things, is a bad way of cleaning them. They should always be first washed in cold water, then in that hot as the hand will bear. A final scalding will render them sweet and clean. Sunshine is desirable when exposure to dust is not an accompaniment.

It is not necessary to use soap about milk vessels. Indeed, it is best to avoid it entirely. Plenty of clear hot water will be all that is required. If they cannot be washed as soon as emptied fill with cold water while standing.

Perhaps the churn is as much neglected as any thing about the indoor dairy work. With wooden ware of any kind great vigilance is required if it is to be kept in the condition which a churn should be. The same churn may be used for years and still smell as sweet as new, if properly cared for. There is not the slighest excuse for anything else.

What has been said in regard to washing milk pails, as soon as used, applies rather more forcibly to the churn. As soon as the butter is removed rinse out with cold water if at all milky inside.

If the butter has been well washed in the churn, and the latter revolved, it may not be necessary to do this, but it will do no harm in any case. Pour in plenty of hot water, the hotter the better, and wash with a stiff brush, which is much preferable to a cloth. Give a final rinsing and turn bottom up if a barrel churn.

Do not leave it tightly closed between churning days. It is best not to do this, or the churn will be liable to get musty.

If you would preserve the neat appearance of the churn, externally, never apply hot water, which ruins the varnish. Wiping with a damp cloth will be all that is required as a general thing.

Constant watchfulness is necessary in regard to all cloths used about the dairy room. Nothing so quickly sours as milky cloths, or those not properly cleansed. These should be renewed every few days at longest.

Remember never to pour hot water over them until they have first been washed in cold. The least neglect will have its effect. If bleached butter or cheese cloth is used, as strainer, renew at the first indication of odor. It costs but five cents the square yard, so there is no excuse for using any but clean, sweet ones.

Never put away the wire gauze strainer, with the least obstruction visible in its meshes. Use a stiff brush here; it is the best possible instrument to reach every spot. If one or more of the cows have an attack of garget, the effects will be seen in she strainer quicker than anywhere else.

Of course no one would knowingly use such milk, but sometimes it is first noticed when it comes to be strained.

Mich. W. C ROCKWOOD.

Butter Making for the Small Dairy.

ED. HOARD'S DAIRYMAN:—While we are all making so much fuss about process butter and the injury it is doing the regular creamery market, suppose we stop and think about the people who originally make the butter out of which the "process" comes.

Is it not a fact that the great mass of material published in the dairy papers, is written over the heads of the plain farmer's wives? If you doubt this, take up a DAIRYMAN and run over the headings of the leading articles, and the shorter ones too, as a rule, and what farmer's wife who makes ten cent butter could tell what it is all about.

Of course every paper is written for the class of people who subscribe for it, and the ten cent woman, as a rule, is not much of a reader; but should there not something be done for her, even if we have to interest the farmer himself to read to her as she does the evening work, and tell her the little inexpensive improvements that she can introduce in her little dairy that will raise the quality and the price of the butter she makes?

Take, for instance, the item of churning. When she has to churn in warm weather, as a rule, she lets the milk stand from 24 to 48 hours, and then skims it very closely, taking off very little skim milk or clabber with the cream.

This represents such small bulk that she must delay the churning three or four days in order to get together enough cream to make a churning. In this way she has fallen into the habit of churning twice a week. She has no ice house, cave or cool cellar to keep the cream in, and perhaps never thinks of lowering it into the well or cistern, but lets it stand around, heated from 75 to 90 degrees, until it has formed into clabber with a sour whey at the bottom.

Now any intelligent dairyman could tell that farmer's wife that the life was already gone out of that cream, and by delay she had lost about ten cents a pound on the quality of the butter.

That, she might say, was an old story, but how was she to remedy matters? Let us see. Time is an important matter in butter making, especially in relation of cream to the quality of the butter. Where milk is set in shallow pans, we may say that, as a rule, if the cream is churned when it is 24 hours old, it will make, say, 20 cent butter—if we wait 24 hours longer before churning, the butter will be worth 15 cents, and 24 hours later, 10 cents, and 24 later, nothing.

Here then we are losing five cents a pound every day we delay churning the cream after it is properly ripened. This the good wife will say is greatly increasing the labor of churning. Let us see about that. Suppose we make the strippings amount to one-third of all the milk the cow gives, and instead of setting that for the cream to rise, we pour it into the cream pail; here we save some labor. I pledge my word, I would rather do seven, or perhaps six, to save working on Sunday, light churnings with the conditions all right, than two large churnings with a heart breaking result of poor, half sour butter.

Suppose during the hot weather this summer, every night before going to bed, you rinse the churn out, pour in the day's supply of cream, set the churn where the cool night air and breezes will get at it, put the top on tight, then take a clean blanket or burlap sacks, dip them in water and put them dripping wet over the churn.

Between the cool air and the evaporation of the water from those sacks, the cream by five o'clock in the morning will, even the warmest nights, be reduced to about 62° or very near the correct temperature for churning, so that fifteen or twenty minutes churning will bring the butter. Six churnings, with such care, would probably not, in the aggregate, require one minute more time, than would the two big churnings done in the middle of the day, and sometimes requiring hours of hard work before the butter comes.

But suppose it does take a little more time, and especially more churn cleaning to do it every day, think of the money and the general satisfaction you get out of an improved quality of butter. Then again, if you will empty the churn just as soon as the butter is taken out of it and rinse it out well with first cold and then hot water, and wipe it dry with a clean cloth, there will be little or no work to keep it clean. If the buttermilk is allowed to dry on the inside of the churn, you can never keep that churn sweet.

Now about taking care of the milk and butter. I am getting 35 cents a pound for my butter, and it costs me no more trouble, as money, to make it, nor as much as it does you to make ten cent butter. When I used crocks, I quit them, and got shallow pans, because crocks will absorb grease. I also found that wooden covers for the crocks soon smelt bad from the old grease in them. I also found that a damp spring house was a sloppy place to walk, and that milk set in shallow pans and kept in a dry airy room at the house, raised as much and better cream, than when set in water. I could tell a long story of a jury trial we once had in New York, to prove this fact. Pure air is more useful than cold air, for good cream raising.

The point is, to skim the milk just as it begins to form clabber at the bottom of the milk. You can tell when this is taking place in several ways, with experience. Tip the can slightly and shake the milk or watch the thermometer during the day. You will soon learn, if you have a thermometer hung just outside the kitchen door, to note the change of temperature, and that will tell you just what the milk is doing, and you must skim it just when it is ripe, that night or day, if you want the best results.

To keep the butter fresh and hard until shipment, get a tin pail or several of them with close fitting tops to put the butter in. Lower these pails into the well, or cistern, or other cool place. It pays well, and sells well, to make the butter into pound lumps, the shape of a brick, and cover each pound with parchment paper, that is very cheap, and adds several cents per pound to its value. A little style pays better than hard work in the dairy. All customers taste more with their eyes than they do with their tongues.

The best cheap milk house is to dig a hole, say twelve feet square and six feet deep around the well, leaving the well in one corner or half out so an out door pump can be put in it. Board or brick up, and put a double roof over this milk house, with windows for light and ventilation. Plant trees on east and south side, two feet apart, and cut out when they get too thick.

Louisville, Ky. L. S. HARDIN.

The Time to Cut Hay.

ED. HOARD'S DAIRYMAN:—I must ask the privilege of raising my voice against what I consider rank heresy in the article on cutting hay by W. J. on page 367 of the DAIRYMAN. It may be an easy question to settle, but my observation is that to cut hay before it is, at least, on the edge of maturity is to cut the crop in two. All forage crops that I know anything about, grow much faster, bulk for bulk, just as they are coming into blossom than at any other time. Cut hay before this time and it will dry away to a very small bulk, not to mention the time it takes to dry it.

Cut hay in full blossom and it is usually very dusty on account of the saving of the stamens of the flowers. Such hay is not fit for horses. A horse with even a slight attack of heaves will cough constantly over such hay. The plan should be, then, to cut hay, especially timothy, just as soon as the blossoms fall and to make enough haste to get through before the seed becomes hard. This will secure the leaves before they begin to wither and it will take the crop at its great est bulk.

I am not trying to say that wood is hay or that the lower end of the stem is best, weight for weight for I know that such is not the case, but my observation is that mere leaf hay, such as aftermath, is not as nutritive as it would seem to be. Cattle eat it with great relish, but they seem to be about as hungry as they were before. One summer we went through a drouth which so cut down the growth of meadows that most of the grass did not head out at all. I went into winter with a very small supply of hay, but with the notion that what there was would go much farther than ordinarily. I was badly mistaken. The hay went off like chaff before the wind and nothing saved the remnant of the stock, but the selling of most of it.

It seems to be a recent discovery, that it is the pith, and not the woody outside of the lower part of the corn stalk that cattle reject. At any rate, it will not do to sacrifice a crop at the very time it is growing fastest. It would be better to cut it higher from the ground, and thus reject the woodiest portion. Cannot some of our experts make us a test on something like these lines? Selecting about three plots of grass of equal promise, let them be cut, one before blossoming, one as late as possible before there is any visible ripening, and the third at some time as nearly half way between the extremes as possible. There will be an extra proportion of wood in the last cutting, of course, but will that not be more than made good by the amount of nutritive matter in the last cutting, and will not the second cutting, also, be worth more than the first?

It may be that such tests have been made, but if I have seen a record of them I do not recall them. What I am insisting on, is quantity in the main, I confess, but at the same time I believe that the quality is not much better in early cut hay, than that which is cut just before it begins to lessen in value. There is more sugar in it, but sugar is by no means the solid food that starch is, though it may be more palatable, and, therefore, deceive the unobserving.

For the sake of illustration, it is proper to take an exaggerated case. Let us cut a part of a field of fodder corn when it is half grown, and the rest when it will not get any larger. Does anybody suppose that the early cutting is as valuable as the other?

Erie Co., N. Y. JOHN CHAMBERLIN.

Eureka Harness Oil is the best preservative of new leather and the best renovator of old leather. It oils, softens, blackens and protects. Use

Eureka Harness Oil

on your best harness, your old harness, and your carriage top, and they will not only look better but wear longer. Sold everywhere in cans—all sizes from half pints to five gallons.

Made by STANDARD OIL CO.

THE returns of the Board of Trade of England, show that on an average 46,000 tons of oleomargarine are exported into that country.

How many tons of butter does the above amount of oleo displace, and what effect does it have on the market price of butter?

DAIRY MARKETS.

ELGIN, Ill., June 26—Butter—Firm; offerings 307 tubs; sales 207 tubs at 18c.

CHICAGO, Ill., June 26—Butter—Creamery extra, 18c; firsts, creameries, 16½@17c; seconds, 13½@14c; Dairies, selections, 15@15½c; No. 1, 14c; No. 2, 12@13c; extra ladles, 12½@13c.

Eggs—Fresh at mark, cases returned, sold at 11@11½c; loss off, cases returned, 12c; duck eggs 9@10c; goose eggs, 12c.

Cheese—Full cream, Twins, new, good to choice, 8¼@8½c; Young Americas, 8¾c; Swiss 11@13¼c; Limburger, 7@8c; Brick, 7½@8¼c.

Cattle—Trade was active, and prices ruled strong at last week's closing quotations, or 10c higher than last Thursday. All classes of buyers purchased freely, especially New York exporters. One load of 1,479 lbs steers sold at 5.65, and a load averaging 1,444 lbs at 5.60. The next highest was 5 50 with the bulk of native beef cattle at 5@5.35, and comparatively few below 4.85. Exporters bought principally at 5.25@5.40; corn-fed western steers 4 60@5.40, distillery steers, 5@5.30; straight Texas steers, 3.65@5.10; Texas cows 3 55; native cows, principally 3 10@4; heifers, 3.90@4 60; distillery bull, 4.15@4 25; veal calves, 5 50@7 and feeding cattle at 3.75@4.95

Bran—In fair request at $11 per ton in bulk, and $12 in sacks f. o. b. and 10.62½ in bulk billed through.

Middlings—Quiet and sold at $12 billed through.

MILWAUKEE, Wis., June 26—Butter—Creamery, fancy prints, per pound, 18c; extras 18c; firsts 16@17c; seconds 14@15c; imitations 14@15c. Dairy, selections, per pound 14@15c; lines 12@13c. Market firm and active for all kinds; receipts 19,090 pounds.

Cheese—American Full Cream, new, choice to fancy, 8@9c. Brick, new, choice, 8@8¼c Limburger, fall, choice, 9@9½c; new choice 7½@8c. Swiss, Drum, choice 12½@13c; Block, choice 10½@11c.

Eggs—Fresh, per doz 12c, loss off, cases returned. Market firm and steady; receipts 348 cases and not equal to demand.

AVOCA, Wis., June 26—Cheese—On the Lone Rock and Muscoda Dairy Board, today, offerings were all taken at 7⅞@8 cents, mostly 8 cents.

FOND DU LAC, Wis., June 26—Cheese—Offerings, 600 Twins, 580 Daisies; market strong; Twins 8¼c; Daisies 8⅝c.

CHILTON, Wis., June 21—The sales of to-day were 30 Twins at 8¼c; 240 at 8c; 80 at 7¾c; 260 Daisies at 8c; 220 cases Young Americas at 8¼c, and 260 at 8c.

PLYMOUTH, Wis., June 20—Sales to day were 1,230 Twins at 8½c and 950 Americas at 8¾c; market active.

MANITOWOC, Wis., June 21.—Offerings of cheese at the Dairy Board of Trade to-day were 750 boxes Daises, 100 boxes of Twins, 800 boxes Young Americas. Sales were 400 Daisies at 7¾c; 350 at 8c; 40 boxes Twins at 7¾c; 60 at 8c; 450 Young Americas at 8¼c.

SHEBOYGAN, FALLS, Wis., June 21.—Sixteen factories were represented on the Call board today and the offerings of 1,324 boxes of cheese were all sold, as follows: Seven hundred and fifty-two cases Young Americas at 8¼c; 90 at 86 10c; 312 twins at 8½c; 170 daisies at 8½c.

APPLETON, Wis., June 15—The offerings on the call board to-day were 632 Twins, and all sold at 8c. Market brisk.

BRILLION, Wis., June 16—Sales of cheese today were 1,526 Daisies, at 7¾c, 817 Twins at 7¾c, and 250 cases Young Americas at 8c and 150 at 8⅛c.

HORTONVILLE, Wis, June 15—Offerings today were 419 Cheddars, and 1,261 Twins. Sales: 123 Cheddars at 7¾c and 1,046 Twins at 8c. Market active.

NEW YORK, June 26—Cheese—State full cream large or small colored, or white, choice, 8¼c.

Eggs—State, Pennsylvania and western, 15@16½c.

FULTON, N. Y., June 19—Cheese—Today 20 factories were represented with 1,735 boxes of cheese. Large sold at 8c, small sold at 8¼c.

BOONEVILLE, N. Y., June 17—Cheese—On the Board today, 1,040 boxes of cheese were offered. Nearly all were sold at the curb. Prices ranged from 7½@7⅞c.

OGDENSBURG, N. Y., June 19—Cheese—On the Board there were 1,733 boxes of cheese offered. There were 196 boxes sold at from 8@8½c. The balance was sold on the street at 8¼c.

CANTON, N. Y., June 19—Cheese—There were 2,236 boxes of cheese offered. Large sold for 8⅛ cents and the small for 8c. There were 1,328 tubs of creamery butter offered. Sales were made at 17¾c.

LITTLE FALLS, N. Y., June 19—Cheese—This market had quite a boom today. Prices are advanced fully one-half cent. The sales are not as large in amount as might naturally be expected with the large production. The sales are as follows: 88 lots, 6,523 boxes at 7⅞@8c.

Butter—Quite an increased amount of butter was brought in today, considerable of it in small packages, all dairy make. It sold at 15@17c, the bulk at 16c.

UTICA, N. Y., June 19—Cheese—The market today showed an advance of ⅞c over last week's price. The sales were nearly 2,300 boxes greater. On the whole, business was quite as satisfactory to the factorymen as it has been this season, and the indications that good prices will be the rule for some time to come. The sales aggregated 114 lots, 8.652 boxes at 8@8½c. The transactions on June 21, 1897, were 11,874 boxes, with 8c the ruling price. The transactions on June 20, 1893, were 8,197 boxes with 6¾c as the ruling price.

The sales of butter to-day were: 21 packages at 17c, 15 packages at 18½c, 30 crates of 1-pound packages at 20c, and 20 crates of 5-pound packages at 20c.

WATERTOWN, N. Y., June 19, —The market on Saturday showed great activity and there was a decided advance in prices. On the board 600 boxes of large were sold at a range of from 8@8¼c, on the curb 5,410 boxes of large white were sold at from 8@8½c and 342 boxes of twins at from 8@8½c.

ST. LOUIS, Mo., June 26—Butter—Quiet; creamery, 15@18¾c; dairy, 12@15c.

Eggs—Firm; 10c.

KANSAS CITY, Mo., June 26—Butter—Creamery 16¼c; dairy 13c.

Eggs—Fresh; 10c.

CINCINNATI, Ohio, June 26—Eggs—Quiet 10c.

Cheese—Firm; good to prime Ohio Fat, 8@8¼c.

Butter—Steady, 19@20c.

NEWARK, N. J., June 26—Market quiet, 18½@18¾c for fancy creameries. Receipts liberal.

WASHINGTON, D. C., June 26—Market steady extras 19c; firsts 18c.

BOSTON, Mass., June 26—Butter—Market very firm, 19c.

Cheese—Steady 8½@9c.

Eggs—Quiet, 14@15c.

NEW ORLEANS, La., June 26—Butter market quiet, 19c.

BALTIMORE, Md., June 26—Butter—Market firm; creamery, separator extra, 20c; extra first, 18@19c; creamery firsts, 17@18c; creamery imitation extra, 15@16c; ladle extra, 14@15c: western store packed, 11½@12½c.

Eggs—Market firm; strictly fresh stock, 14@14½c.

PHILADELPHIA, Pa., June 26—Butter—Separator creamery extras, 19c; creamery firsts, 18c; seconds, 16@17c; imitation creamery, extras, 16c; firsts, 15c; seconds, 13c. Ladle packed extras, 14c; firsts, 13½c; seconds, 13c. Print butter, creamery extras, 20c; firsts, 19c; seconds, 16@18c.

Eggs—Pennsylvania and near by, 14½c; western, 14½c; southwestern, 14c; southern, 13½c.

ST. LOUIS, Mo., June 26—Butter—Quiet; creamery, 15@18½c; dairy, 12@15c.

Eggs—Firm; 10c.

NEW YORK MARKET.

NEW YORK, June 24—Butter—Receipts for the week, 66,004 packages; exports for the week, 1,986 packages.

Receipts continue heavy, about the same as last year, while prices all through the month have ruled fully 1½@2c per pound higher than last June.

Home trade has been without speculation and confined to current daily wants. There is an absence of export buying and almost a cessation of foreign shipments of fine creamery butter. The entire exports this week were made up of good to fine ladle goods bought at 13½@14½c. Large lines of creamery butter went into freezers because receivers were unable to turn them at any profit. We quote:

Creamery, extra 18½c; medium 17@18c; poor 15@16c. Dairy, extra 17@17½c; medium 15@16c; poor 18@14c.

Cheese—Receipts for the week, 34 019 boxes; exports for the week, 6,337 boxes.

Export and speculative buying absorbed the week's receipts and the market closes firm at outside quotations. Large cheese sold at 8¼@8¾c, the latter for finest white. Small sizes were taken by local buyers at 8¾@8½c for the best marks, and 8@8½c for less desirable lots. Light skims were inquired for and sold at 6@7c. We quote:

Full cream, large, extra 8¼@8½c; medium 7¾@8c: poor 6½@7c. Full cream, small, extra 8¼@8½c; medium 8@8½c; poor 6½@7c.

Eggs—Receipts for the week, 65,231 cases. Free receipts caused a trifle easier feeling, and for all kinds except the very finest marks, lower prices. We quote:

New York & Penn., finest marks, per doz. 15½@16c; Northern & Western, finest marks, per doz. 15c; Other sec., fair to good marks, 13@14½c.

DAVID W. LEWIS & Co.
177 Chambers St.

BALTIMORE MARKET.

BALTIMORE, June 22—Butter—The receipts of separator creamery butter the past week have principally come from what is known to the trade as the Elgin district, and consist largely of the highest grades; but the proportion of true extras is smaller than expected at this season, and the trade are at a loss for a satisfactory reason. The bulk of this variety of creamery butter, on the high standard adopted in some of our neighboring cities, would about measure up to 92 points, consequently it is right hard to sell when expectations run high in harmony with the advanced prices. The demand now is almost exclusively for consumption; whatever sales are made to go into the freezers are to retail dealers for distribution to consumers later on; not one per cent. is speculation pure and simple. Now with gathered cream and imitation creameries and ladle packed, conditions are different, and the grading no better nor worse than normal, and though the prices are perhaps relatively as much higher as the prices of separator creameries over last year, still prime cost and expense of carrying added put them at a price where they can be jobbed out at a profit and still give the retailer a chance, and all within the limit of a modest purse later on. Out-of town trade is but scantily represented here, and the exporters have withdawn from the market on all but regular orders and lowest grades. The supply of storepacked butter is insufficient for trade wants; there is a quick demand for all grades of it.

Creamery separator, extras, 16c; firsts, 18c; seconds, 17c. Creamery gathered cream, extras, 18c, firsts, 17; seconds, 16. Creamery Ohio, extras 18c; firsts, 17c; seconds, 16c. Creamery Imitation, extras 16c; firsts, 15c; seconds 14c. Iowa & N. W. Ladle, extras 14c; firsts, 13c; seconds, 12c. Ohio & Indiana Ladle, extras, 14c; firsts, 13c; seconds, 12c. Ohio storepacked, extras, 12c; firsts, 11½; W. Va. storepacked, extras, 12c; firsts, 11½c. Creamery blocks (2lb.) extras, 21c; firsts, 20c; seconds, 19c. Creamery prints (½lb.) extras, 21c; firsts, 20c; seconds 19c. Md., Va. & Penna. prints, extras, 19c; firsts, 18c; seconds, 16@17c.

Eggs—There is quite a scarcity of choice fresh eggs; for this kind there is a quick demand at advanced prices; our market rules firm on all choice stock at 14 cents. Heated or other faulty stock are not included in our quotations.

Notice—Mr. Shipper, Dear Sir:—We feel satisfied were you to see the miserable condition in which some eggs arrive packed in barrels and boxes that you would become convinced that cases are far better, and the loss is not near as heavy as it is in barrels and boxes.

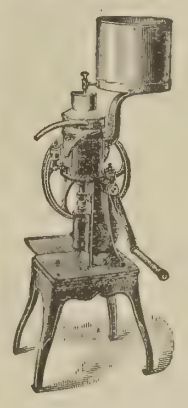
Western Md. and Penna, per doz., 14c. Eastern Shore (Md. and Va., per doz, 14c. Virginia, 14c. Western & W. V. 14c. Southern, 14c. Guinea, 7c.

Cheese—While the receipts are ample at present for all requirements, the market is firm as quoted; demand good. N. Y. State—Cheddars, fine 8¾c; choice, 8½c fair, 8@8¼c; N. Y. State—flats, fine, 8¾@9c, choice, 8½c, fair, 8¼c; N. Y. State small, fine 9@9¼c, choice 8½c, fair, 8¼c. Ohio—flats, fine, 8@8¼c; choice, 8c; fair, 7½c; picnic, Ohio fine, 9c; choice, 8½c; fair, 8c. Skims, fine, 6½@7; choice, 6@6¼; fair, 5. Swiss cheese, fine, 13¾@14; choice, 12@13; fair, 10@11.

301 Exchange Place. G. M. LAMB & BROS.

Latest quotations for fancy creamery: Buffalo 19c; St. Paul 17½c; Minneapolis 17c; Detroit 19c.

FOREIGN MARKET.



BOSTON, June 24—Cable advices of this date from the principal markets of Great Britain to Geo. A. Cochrane give butter markets as decidedly steadier with a slight advance in the better descriptions of all kinds of butter. Danish is selling at 20@21c, finest Irish 18½@19c. Arrivals of Canadian are increasing but with improved quality receivers are asking more money. Sales have been made this week at 18½@19c in boxes, with some refusing to sell at these rates. There is a little better feeling in low grades and finest ladles would probably sell at 14@14½c.

Cheese markets are all the turn steadier. Current arrivals of American and Canadian are selling at 9@9½c. The higher CIF quotations from United States and Canada has caused a firmer feeling.

LIVERPOOL, June 26—Butter—United States finest, nominal; good 62s.

Cheese—American finest white, 42s 6d; colored 42s; ordinary new, 43s 6d.

"Electricity" vs. "Gas" in CREAM SEPARATORS

Protective patents prevent the use of the improved "Alpha" disc or divided milk-strata system in any other than the De Laval separators. Other fairly well made centrifugal separators are as gas to candle and save $3.– to $5.– per cow per year compared with setting methods. The De Laval machines are as electricity to gas compared with other separators and save $3.– to $5.– per cow per year *over such other machines*, and $5.– to $10.– over gravity processes.

A new 1899 De Laval catalogue, to be had for the asking, tells the whole story.

Exceptionally Low Rates to Richmond, Va., via the North-Western Line. Excursion tickets will be sold at greatly reduced rates from all stations, July 10, 11 and 12 (but not for trains arriving Chicago before July 11 or later than July 13), limited to August 15, 1899, inclusive, on account of National Convention B. Y. P. U. Apply to agents Chicago & North-Western R.y. 20-2

Special Excursion Rates to Portland, Ore., and other North Pacific and Coast Points. —Via the North-Western Line. Excursion tickets will be sold at greatly reduced rates from all stations, until July 8, inclusive, limited to September 4, 1899, inclusive. Variable routes, delightful scenery. Apply to agents Chicago & North-Western Railway. 20-2

The Pure Milk Supply Problem.

ED. HOARD'S DAIRYMAN:—Week after week notices are found in the German papers stating the establishment of new concerns for the supply of pure milk. Thus in Berlin, where thus far the peddling from wagons has mainly been done by the large firm Bolle, a new company is being established by two former employers of said firm and a "moneyman", who will operate a large dairy in the west end of Berlin, after the Bolle pattern.

The proprietors of the many milk stores in Berlin are much excited over this new competitor, which still makes them fear a further decline in milk prices. It also seems queer to us over here, who have the idea of a perfect indifference on the part of the Germans as to the keeping of the Sabbath, and who are always in fear of the Continental Sunday, that it even can be suggested in Berlin to forbid the loading of empty milk cans on the wagons for returning to the rail road stations, as being a cause of "disturbing the Sunday quiet." This complaint, though, was considered unreasonable by the court, as prohibitions in that line would cause great inconvenience as to the necessary supply of milk.

SCHWEIZERHOF

is the name of still another establishment just started by H. Schlegel, who, years ago, received the patent rights of Neubans, Grouwald & Co., for sterilization. The supply of Berlin with special health milk, according to the "Gartner" method, will be the main object.

PREPARATION OF "CHILDREN'S MILK" AT CO-OPERATIVE CREAMERIES.

The Stedinge Creamery Co., at Berne, Oldenburg, has, during this year, prepared "children's milk" according to the method of "Backhaus", and the demand has so far exceeded all expectations, that a separate building for that purpose in connection with the creamery has become a necessity. During the first month, February, the sale was 575 quarts; in August, 4,300, and was expected to exceed 6,000 quarts in September.

It is a proof of the highly enjoyable part that the public already knows how to appreciate the advantage of the Backhaus children's milk as an infant food. The Stedinger creamery received a special big send-off, as the last born Oldenburg Prince was fed on the same, from the very first day of his life!

The new building has been decided upon, and the manager in charge will be sent to take a special course in "health and children's milk preparations" at the University of Konigsberg, the instructor being Prof. Backhaus himself.

"What do we care what those Germans do?" some will say. I think it would be very well for some of us, if we would care. Thus far the supply of an absolutely healthy and properly prepared milk for feeding young children has been all together inadequate, or, rather, not to be had at all, even for money. A few so-called laboratories have been established, some, like Mr. Strauss, furnishing pasteurized and modified milk so cheap that the poorest could get it; some, again, furnishing such at so high figures, as only making it possible for the well to do to buy it; both movements are well enough as far as they go. But not until such milk is produced and put up on so large a scale, as to make it possible to make it a paying business, and at the same time to furnish such milk at prices within the reach of all. Not until then will all these efforts accomplish what they ought and must some time.

The Germans cannot produce cheaper or better milk than we, and the people there, on the average, possess less means than our people. Why is it then, that the slow going Germans so quickly take hold of a good thing? Is it because the public there generally are better instructed along these lines? If so, it is time for us to do likewise.

SUPPLY AND CONTROL OF MILK IN COPENHAGEN.

The following is mainly an extract from a report by the Health Commission specially prepared for the Agricultural Congress at Stockholm. While we, in various papers, have had full descriptions of the well known "Milk Supply" of Mr. Busck, still we have so far heard very little about other prominent milk companies there, as well as other supply sources.

Copenhagen gets its milk partly by rail, partly by steamboats, partly by wagons and finally also from dairies which keep cows in the city. The farthest distance milk comes by rail to Copenhagen is from the Island Fyen, or about 100 miles, and then it has to cross the Belt by boat. The large milk supply firms furnish their own specially arranged cars with refrigerator; the rest ship their milk by the ordinary railroad cars in tin cans.

By wagons the milk comes only from a two or four mile distance, and is peddled from house to house by the farmers.

The milk produced in Copenhagen is getting less every year. Thus in 1866 the number of cows kept in the city was 3,156; in 1889 only 1,450, and in 1895 only 964, an insignificant number for a city of 400,000 people.

Milk is shipped by steamboat across the sound from Sweden; but this is mainly skimmed milk intended for bakeries.

Besides the "Copenhagen Milk Supply" we find another large stock company, "Milk Supply Pasteur" which deals exclusively in pasteurized milk in pint and quart bottles. The milk is not pasteurized in the bottles, but in an apparatus, then cooled and bottled afterwards.

THE DANISH MILK COMPANY (CASSE SYSTEM)

is a wholesale business with a temporary transaction of about 25,000 quarts daily, being a comparatively new business. The milk comes from the island, of Fyen, where it is collected at two large creameries and pasteurized and cooled. The system for pasteurization used by Mr. Casse differs from all others. The milk is all run through a system of pipes surrounded by hot water, and heated to the high temperature of 185° F. (85° Cent.) and yet does not taste perceptibly cooked. But what is meant by perceptibly? From the heating pipes the milk is conducted into pipes with cold water surrounding, and finally ice-water tanks; the milk being absolutely excluded from any contact with the air during the whole process. While Mr. Casses' business is new in Copenhagen he has for years shipped pasteurized, partly frozen milk to England, very successfully. But while I admit that milk intended for long keeping, say for weeks, should not be exposed to the air at all, still this will be of slight significance in regard to milk intended for daily sale, provided the air is fresh and pure where the bottling or canning of the milk takes place. Of late, Mr. Casse has also begun to supply pasteurized milk in bottles.

Lastly must be mentioned the stock company "Copenhagen Dairy", established 1874, which sells milk exclusively from milk stores, and which of late also has introduced veterinary examination of the cows and pasteurization of the milk. Condensed milk from

THE DANISH MILK CONDENSING COMPANY

of Hillerod, 16 miles from Copenhagen, is also for sale in the city, but is only little used by the city people. The whole milk fresh from the cows is sterilized and in a vacuum pan condensed to ⅓ of its original volume and put up in tin cans. As to the

CONTROL OF THE MILK:

it was formerly done by the lactometer, but this being a very uncertain method has been abandoned. The present mode is to buy samples several times a week and these are at once examined and analyzed at the laboratory of the health board. Does the milk contain less than 2.5 per cent fat (a very low per cent indeed), the health board will take samples at the stable of the dealer, and compare the fat per cent, which then serves as a guide for further investigations? The tables compiled by the health board show an increase of the average fat per cent contained from the year 1888 of only 2.12 to 3.86 in 1895.

Adulteration with water was very rare, and the manipulation generally consisted in partly skimming or adding of skim milk to whole milk or both. Remarkable is the fact that in no case has it been proven that any kind of chemicals have been used for the perservation of milk or cream, which certainly speaks well for the conscientiousness of the Danish milk producers and dealers. It is, sad to relate, something that cannot be said of dealers and producers in this country. A lesson which the health boards of our cities might do well to learn, is that frequent examinations also are made as to contents of dirt and the number of germs contained in non pasteurized as well as in pasteurized milk.

Inoculation of milk offered for sale in Copenhagen, has also been performed on rabbits in order to prove the presence of tubercle bacilli.

Very strict regulations are also given by the Health Board as to the keeping of cows in the city; but outside the city it has no control whatever, for which reason it is highly desirable that the initiative in this direction may be taken more and more by private concerns and especially by the large dealers. In cases where the claim for such control is made for advertising purposes the jurisdiction has the right to examine whether the claim is in agreement with actual conditions, and to prosecute where such is not the case; which already has frequently happened in Copenhagen.

As the rules given by the health board for keeping cows in Copenhagen seem to me to be of considerable interest for us in a general way, they are given here in full:

REGULATIONS FOR KEEPING AND CARE OF COWS WHOSE MILK IS INTENDED FOR CITY SUPPLY.

1. The walls and ceilings of the stables must be kept free from dirt and spiderwebs and must be whitewashed every spring and fall.

2. Just before milking the stable must be cleaned and aired and the walk behind the cows washed out. At least once daily, dry and clean bedding must be provided

3. Before beginning to milk, the bag, the teats and the nearest parts of the body must be well rubbed off. In case of washing, it must be done so early, that the skin and hair covering may dry perfectly, so that the wiping, anyhow, may be done just before milking.

4. During milking, which must be done with clean hands, the tails of the cows must be tied up or to one side, so that no dirt from the same can be thrown into the milk pail; unless the hair is cut short at the lower end of the tail, and the same is carefully cleaned.

5. Pails, cans and other implements with which the milk comes in contact, must always be kept carefully cleaned. The milk must be run through a sufficiently fine strainer into the can, which during milking must be placed outside the stable.

6. Cows afflicted with sores, inflammation or tuberculous swellings on the teats, or which have to be treated on these places with remedies which cause swelling or are poisonous, must be milked separately; if the disease is of a tuberculous character, then the cows must be separated entirely from the rest. The milk from such must neither be sold separately nor mixed with other milk, nor be used as human food, neither must such be milked on the floor in the stable. Only when boiled may such milk be fed to other animals.

7. Cows with any kind of emanations of a stinking, sickly character (foulness of the sheath, retaining of the afterbirth) or afflicted by tuberculosis, should as much as possible be separated from the other cows; the place where they have stood must be thoroughly cleaned and disinfected by boiling water and cardolic water of 5 per cent. Their milk may only be used as stated in No. 6.

8. Persons having eczema or moist sores on their hands, are not allowed to milk. The same holds good as to persons who short time before have been in contact with people who had dysentery, typhus, rose fever, diphtheria, scarlet fever, or other infectious diseases, or with animals afflicted with serious infectious diseases, and never before thorough disinfection.

Persons suffering from any of above named diseases, or consumptives, must neither be employed as milkers nor to take care of the cows.

It would indeed be a great gain, if such rules, might be more generally observed, not merely in regard to city milk supply.

Washington, D. C.

Mr. Wheaton's Canadian Dairy Notes.

Quality of Agricultural Products.—Butter and Cheese Makers.—Quality of Milk Supplied.—Cheese and Butter Situation

ED. HOARD'S DAIRYMAN:—The month of June, so far, has, on the whole, been a very favorable one for cheese and butter making. The nights have been cool, and cows have had plenty of good, succulent food with no drawback in the way of a scarcity of water. With these favorable conditions every factory should be able to turn out a fine quality of either cheese or butter.

The whole success of the business centers around this word *quality*. When one thinks of it, it is surprising how closely agriculture in general, is associated with this one word. No farmer can hope to succeed in any branch of his calling, unless he gives special attention to having the quality of the product he turns out, whether it is in grain, feed, live stock, butter, cheese, etc., of the very best.

In this respect, the farmer is differently situated to that of the business man or manufacturer. For instance, a manufacturer may decide to turn out an inferior quality of goods, which he can afford to sell for a lower price; and he can make a profit out of the transaction, because these inferior goods do not cost so much to produce, as a superior quality. A maker of bicycles will turn out small grades of wheels, which he sells at different prices, and makes the same profit out of each one, just because the lower grade wheel does not cost so much to produce as the higher grade.

But the farmer, or to particularize, the dairyman cannot conduct his business in that way, and make a profit out of it. He can not lay out his work beforehand, and plan to produce different grades of butter, unless he resorts to fraud butter, which he can sell at different prices, and have the same profit on each lot. Why? Because it will cost the same to produce each grade of butter. While there may be a variation of from five to ten cents per pound, in the prices for which the different grades sell for, there will not be the same variation in the cost of production of the different grades of butter. Everything considered, it will cost as much to produce a pound of poor butter as of good butter, and while the latter may be sold so as to return a good profit, the former may have to be sold at a loss.

The same law will apply to good and bad cheese, good and bad cows, good and bad live stock, and, in fact, through the whole category of products produced on the farm. Is it any wonder then, when we see so many inferior farm products put upon the market, that many who follow the occupation of the farmer fail to make their business a success.

In this regard the position of the agriculturist is, indeed, unique, unless he grasps the real signifiance of this fact, and puts it into actual practice, he cannot hope to succeed in these days of pure competition in the world's food markets. As a rule the consumer, in nearly every country, is always ready and willing to pay a little more for superior quality in the food which he eats—a point which every producer of food products should bear in mind.

But to return to where we started, and apply this principle to the cheese and butter produced in our factories at the present time. How many factories are there concerned in getting the best quality of product. We have the maker, the owner of the factory, or the company, and the patron. All these are vitally interested or should be, in turning out nothing but the very best quality of cheese or butter.

While some makers may be incompetent,

and neglectful in regard to their duties, we do not think their number, comparatively speaking, is as large as the number of patrons who are neglectful and careless about the milk they send to the factory. And this is the strangest part of the whole business. For if an inferior quality of product is turned out, and it has to be sold at a cent or half a cent a pound less than the best quality, it is the patron who is the loser, unless it be that the maker has to make the loss good, whether he is to blame or not.

And it is also surprising how many patrons slip in behind this loop hole of escape, and saddle the whole loss upon the maker, and if need be take his last cent in order to recoup themselves for any loss sustained from inferior cheese being made. If the maker is wholly to blame, all well and good. But we question, if all the facts were known in connection with the loses, which many cheese makers have made good during the past year or two, whether they were the guilty parties, and if the full blame should not have rested upon delinquent patrons, who neglected to take care of the milk they supplied their maker with.

There are factories in this country where the finest quality of cheese and butter is turned out every day in the year. And one of the reasons for this, is that the patrons of these factories know how to take care of their milk properly and endeavor to co-operate with the maker in supplying him with the best quality of raw material for making the highest quality of product. In this we have the essential feature of our co-operative dairy system brought out, in that everyone interested is doing his utmost to make the quality of the product the very best.

In appealing thus strongly to the man who supplies the raw material, we do not wish to considered as in any way condoning any faults or failings of the maker. He may have many; but as far as our knowledge of makers goes, they are more ready and willing to take advice and act upon it than the average patron. Of course the latter is harder to reach, and when you do get at him he is not always in a receptive mood to receive the advice and information tendered him in regard to conducting his own part of the co-operative system in the best way. And then there are 100 patrons to one maker, which makes them 100 times harder to reach, and necessitates that they be talked and written to a good deal more than the man in the factory—a thing that must be done if the highest quality in the product is to be obtained.

The market during the past week or two has been somewhat irregular. Lower cables have been reported and yet the market on this side has ruled strong during the week (June 17th) with a stiffening in prices. The lower prices in England have increased consumption and produced a steadier feeling. But it is claimed that the higher prices, which are now being paid at the local cheese market, here, are caused by short sales and that the cheese situation is not so healthy as it would otherwise be.

Some in the trade, who are in favor of this short selling, are endeavoring to make it appear that this practice is a good thing for the farmer, in that it enables him to get a higher price for his cheese. While this for the time being may be true, yet it must be remembered that a time will come when the dealer has filled his short sales, and when it will be to his interest to hold off awhile and endeavor to make up for any loss sustained by getting prices down as low as possible.

The make continues to grow. From May 1st to June 14th our exports were 100,000 boxes more than for the same period last year. About all May goods are out of the factorymen's hands. At the local markets last week a great variation of prices prevailed, ranging from 7½c to 8 9-16c per lb. Early in the week the market ruled very little over 8 cents but towards the end prices advanced from ⅛ to ¼c per lb. All of which is encouraging the salesmen to hold June goods awhile.

There has been considerable activity in the butter market lately and 18c to 18½c have been paid in some districts for choice, fresh, creamery butter. The butter, in whole sections, has been taken at 18c, which considering everything is a good figure. The bulk of this butter is reported to be going into cold storage on English speculative account. There must be something like this going on, as the above prices are too high to admit of an export business being done at present cable prices.

The butter situation on the whole is good. Our exports of creamery butter have increased over 11,000 packages during the six weeks ending June 14th as compared with the same period last year, and if this ratio continues till the end of the season, 1899 will be a record breaker in regard to our export butter trade.

Toronto, Canada.

The Chicken-Mite.

[Press Bulletin.]

This exceedingly troublesome and often fatal pest is the cause of many complaints from those raising chickens. The attacks of the pest are not confined to poultry, as it is often found in pigeon houses and in the nests of other birds about farm buildings. Where they are numerous they often find their way to animals confined in the infested buildings. The mites are nocturnal in their habits. During the day time, they are generally in hiding about the building, but at night they abandon their hiding places and seek for food. Chickens are often prevented from sleeping at night, and not rarely forced to abandon their eggs when setting. Instances have been recorded where birds have been killed by this mite.

There is no way to receive permanent relief from the pest. The remedies must be applied often and thoroughly, since the insect is able to live a long time without eating. Cleanliness must be observed. The hen manure should be frequenty removed, as it often swarms with the pest. If the hen house is light, fumigation by sulphur is very effective. To prevent any accident by fire, float the metal vessel containing the burning sulphur in a tub of water. After several hours of fumigation, air the building well before occupancy. Pure kerosene is also to be recommended. The interior of the building, including perches, should be well sprayed with it. After using kerosene, remember to air the building before introducing a light.

P. J. PARROTT.
Kansas State Agricultural College.

The JERSEY MILK CAN

A Strong, Well Shaped and Well Finished Milk Can at a low price.

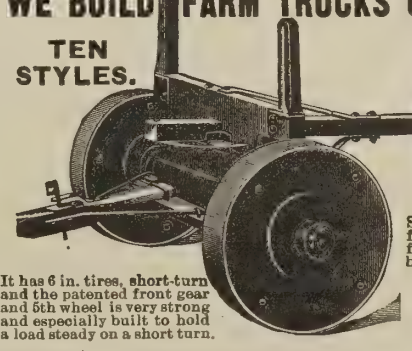
This can has our "Victor" Can Breast, is perfectly shaped, will not leak, and has no crevices inside where milk can lodge and sour and smell. Capacity five, eight or ten gallons.

THE MILK CAN TRADE MARK IS ON EVERY CAN.

If your dealer has not got them, we will ship on receipt of your order. Write for our Handbook No. 32, "A Study in Milk Cans."

BUHL STAMPING CO., Detroit, Mich.
Mention HOARD'S DAIRYMAN.

Gluten Feed is used by nearly all successful dairymen, and has become a necessary article for any dairyman farmer who wishes to keep pace with the successful men in his line of business.



Gluten Feed increases the flow of milk, improves the quality, keeps the cattle in the best possible condition—in fact, helps you make more money out of your dairy. This is not cheap talk. We mean business. Gluten Feed is all and more than we claim for it, and, best of all, a trial proves it.

Sample of Gluten Feed, Milk Talk Pamphlet, and circular illustrating "Value of Butter Fat in Milk," all FREE if you address

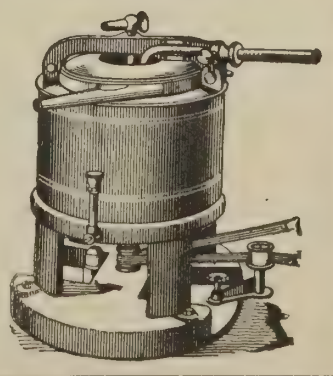
SAGINAW, MICH.



Do You Get Perfect Milk?

Do all your patrons bring absolutely perfect milk? If not, you can't get perfect results unless you have a pasteurizer. Pasteurization overcomes the effects of careless handling of milk and careless cleaning of cans and utensils. It removes all danger of bacteria, improves the quality of the cream and of the butter made from it and makes both keep longer.

THE REID Pasteurizer

affords the most scientific, most practical and economical means of pasteurizing whole milk, skim milk, or cream. Full information and the Reid Long Spindle Separator Book mailed free.

A. H. REID, 30th & Market Sts., PHILADELPHIA, PA. and CEDAR RAPIDS, IOWA.

Concerning That Old "Cow Census."

ED. HOARD'S DAIYMAN:—Under the heading of "Agricultural" in a copy of the *Tribune* October 26, last, which a neighbor recently handed me was the text: "Cost of a Quart of Milk or Pound of Butter," under which was the name of the writer—J. W. Ingham. That old Ellisburgh "Cow Census" of mine, taken just ten years previous, and which you have mentioned from time to time since, was the basis for the efforts; but one would never know from reading the articles, whether that census was taken that month, or year, or in 1776, as no mention of dates is given.

The writer had, evidently, obtained a copy of some paper which contained my last census letter—the summing up of the work—to the DAIRYMAN, from which he caught his inspiration. Had he read each of the seventeen letters I wrote to the DAIRYMAN, nearly all of which contained statements for comparison; or, had he consulted the whole list of 367—I think that was the number of dairymen in the town—possibly he would never have worded the article as he did, it being almost wholly devoted to showings, or trying to show that the cost of keeping those Ellisburgh cows was far too much, while the receipts were much too small.

He did not, however, say much about the butter and cheese receipts, but figured the manure as the most valuable item. In short, he valued the manure at $58.40 per cow, or $26.66 more than was received for butter, cheese, calves and pork from these cows.

The estimate—$58.40 per cow—was based on Prof. Robert s report of feeding three cows at Cornell, the manure from which was all saved, weighed and analyzed, its commercial value obtained, but which, as evidence to show that my figures were wrong, is wholly valueless, as it will not apply to the Ellisburgh farms at all. But I am going to quote some of the statements in the article, and comment on them in their order. He "opens up" by saying:

"One of the first questions asked of a dairyman, after he has delivered his address, at a farmers' institute is: 'How much does it cost to make a quart of milk or a pound of butter?' And, if the dairyman has not counted the cost beforehand, the question will be a stumper."

If he had written: "asked by some dairymen," instead of "of a dairyman," he would have been quite correct. Doubtless, I have heard that question asked or read in fifty of the four hundred institutes I have attended in this state, since I took that census. But one might as well ask the question: "How long is a piece of string," or "how large is a piece of chalk?' Circumstances, localities, cows, conditions and the cost of cattle foods must all be considered in determining the cost of a dairy product; but it may be arrived at, as thousands of farmers, as well as many experiment station directors can truthfully testify. There is no trouble about it, and every farmer, if he will, may know just how much each pound of butter or cheese, quart of milk, calf, or pound of pork costs him.

The next statement he makes, it will be seen, is quite inconsistent:

"The exact cost of a quart of milk or a pound of butter on the farm is a sum which can never be accurately determined. It differs in different states, in different localities in the same state, on different farms in the same locality, and on the same farm with different cows and at different seasons of the year. There are so many different factors that enter into the account, and must be taken into consideration that it makes the problem a difficult one to solve. The cost will depend on the value of the land on which the cows are kept, the value of the cow, *i. e.*, what they cost or would sell for; the value of the calf, the value of the feed consumed (whether raised or purchased), the cost of labor and the value of the manure."

Just what localities have to do with determining the cost of a dairy product, except to cheapen or enhance it, is not explained. A bushel of oats or corn, a ton of hay or silage, or one of bran or other cattle foods, may cost more or less in one town or state than in another, as is usually the case, but that fact does not interfere in working out the problem. All the dairyman has to do is to weigh the foods he gives his cows and charge them with the cost. If he raises all the grain he feeds, he should charge the market price for them. If oats are selling for 30 cents and corn for 50 cents per bushel, he should charge those prices for these foods. If he buys them, he should charge up the price he pays.

In the Ellisburgh cow census prices varied somewhat, according to the value of the farms. On some farms, two acres of pasture were required for a cow; on some, as many as three acres. As a rule, the charge for pasture was from $7 to $10 per cow, for 26 weeks, while hay was figured at $10 per ton, although it was really worth more. There were but two silos in town, then.

In determining the cost of the grain ration, great pains was taken. Indeed, that item was the only difficult one to arrive at, and it was often necessary to refer to the threshing bills, to find out how much grain was grown, then deduct the seed, the amount sold and that fed to horses and other animals, in order to ascertain the cost of the grain ration for the cows. As a rule, however, the figures obtained were quite accurate, as the figures obtained by Mr. George T. Powell and myself in the Bovina cow census, subsquently, as well as those from 130 dairies in the best portion of Ellisburgh, three years since, clearly show. It is my belief, however, that the cost of keep was fully $1 per cow too low in some dairies, as it was the practice of nearly every low grade dairyman to figure his grain ration very low, as soon as he saw that his receipts were low. And I am as fully convinced that the receipts were too high as given in many of these poor dairies, the claim always being made that a large amount of butter, cream and milk was consumed in their families.

"The cost of the calf" had nothing to do with the cost of a pound of cheese or milk, but its value was always added to the other revenues. Except in thoroughbred herds, no cost for service was deducted, while the value of the calves raised was always—except in the case of thoroughbreds—given as the same as of those sold for veals, the cow having credit until the calf went to grass. Sometimes, where inferior pure bloods were sold as veals, however, this rule changed, because such calves always brought less than those raised were figured at.

In arriving at the receipts, it was necessary to go through the books of thirteen cheese factories and a creamery in the town, and those of six factories in adjoining towns. Also, the books of three calf buyers, as there were a number of patrons of each factory who could not tell how much their dividends were; how many calves they sold, or the price received.

The value of the skim milk was included—as was that of the whey—in the calf and pig items; but no credit was given for manure, nor was there any charge made for drawing milk and whey to and from the factories, which would have added $1 per cow to the expense account. The manure went to offset the cost of caring for the cows, and other expense items, but was not enough—since the value of the average farm manure, as every one at all familiar with the situation knows, is not more than one-fourth as much as it ought to be. As a rule, the liquids in the average stable are all lost, and, as they contain 60% of the value of the voidings, but 40% is left. But on most farms, the solids are thrown out and left to waste under the eaves of the stable; so that, when drawn out in March or April, fully 20% of those are lost.

At Cornell all the voidings were saved, while the cows were fed on nitrogenous foods—those which make highly concentrated manure. The writer next gives the senior editor of the DAIRYMAN a whack:

"Ex-Governor Hoard and other dairy authorities have repeatedly declared that more than half-the cows kept in the United States are kept at a loss—boarders with unbounded stomachs, who devour food like Pharaoh's lean kine, and do not pay their board bills. This is putting the matter rather too strongly. Some people talk to create a sensation. They think it necessary to use strong language in order to arrest farmers' attention and set them to thinking."

The Governor knows whether he made the statement or not, but I have heard Prof. Roberts say that the greatest blessing that could come to the dairymen of this state would be about 500,000 cow funerals, which would mean those of one-third of the cows in the state, at the time he made the statement. "More money," he said, "would be found in the farmer's pockets, at the end of the year, if one-third of their herds were selected, taken out and shot, and, if no other use could be found for them, dumped into the fertilizer or compost pile."

They are the third that not only refuse to pay for what they eat, but persist in eating up the revenues, or a part of them, from the other two-thirds. The *Tribune* writer may not know this fact, but he ought to, and may, if he will make proper inquiries.

He says that Professor Roberts gave the cost of the keep of the three cows spoken of, at twenty-three cents per day. This would amount to $83 95 per year. But he estimated the manure at $58.40, which would leave a net cost of $25.55 as against an average of $36.30 for the 5,507 cows in Ellisburgh But, as it is a conservative assertion, to say that the average dairyman in this town does not receive $10 per cow for her manure, it will be seen that the *Tribune's* comparison is not at all a fair one.

Instead, however, of its costing the Ellisburgh dairyman twenty-three cents a day for

Service Bull,
Pedro's Handsome Prince, No. 42794.
The cows in this herd are of the best families of milk and butter producers. We have for sale young bulls by Pedro's Handsome Prince and Exile of St. Lambert 55, No. 36073, out of tested cows. Write for prices and pedigrees.

keeping their cows, it cost them but a fraction over ten cents.

Mr. Ingham closes his article by giving the cost of keep of several dairies in different localities as follows:

"J B. Phelps, of Conneautville, Pennsylvania, one of the vice-presidents of the Pennsylvania State Dairyman's Association says: 'I keep my cows on three cents' worth of ensilage and one cent's worth of wheat bran, making but four cents per day for the maintenance of each cow, or $14.60 per year.' In an essay read at Viroqua, Wisconsin, by Dr C. V. Porter, it is stated that the yearly cost of keeping each cow of his herd of twenty-eight animals was about $25, or less than seven cents per day. This is $11.30 less per year, than the cows reported from Ellisburgh."

No statement is made as to the condition of Mr. Phelps' cows when spring came to their relief, or whether they were giving milk, or were dry, but it is safe to say that they must have had wonderfully strong constitutions, and the winter a short one, to have survived on three cent's worth of ensilage and one cent's worth of bran per day. For cheapness of keeping a herd of dairy cows, Mr. Phelps takes the cake.

We have some pretty close fisted dairymen in this town, and who are so stingy that they have to pull their cows up by their tails in the spring, and who allow them to become so poor that lice can't find grazing ground on their skeletons. But they can't figure on six months' winter keep for $7.52. It will break their hearts, however, when they see Phelps' statement, if they ever do.

But here is one from Wisconsin, and the University, at that:

"An experiment made by Prof. L.H. Adams, of the Wisconsin University, gave the following results: Four thousand nine hundred and sixty pounds of ensilage made 1,688 pounds of milk, that churned 62 pounds and 3 ounces of butter. The ensilage was valued at $2.50 per ton. Counting nothing for labor and allowing nothing for skim milk and manure, his butter cost him a fraction less than 10 cents per pound."

Has all the work of HOARD'S DAIRYMAN, Prof. Henry, Prof. Woll and others, in Wisconsin, been in vain? Is it a truth that a professor in your university feeds nothing but ensilage to cows in milk?

Ensilage is quoted at $2 50 per ton, but as no other foods were fed, it must have been as Sam Weller said of his peas pudding: "Werry fillin' for the price." At 50 pounds per day, one ton would keep a cow 40 days.

Divide $2.50 by 40 and you have 6¼ cents per day. But that is a picnic ration, when compared with Phelps', and ought to make the latter's bones sigh for pastures they know not of.

One more authority for cheap rations closes the article. He quotes a Pennsylvania dairyman, a Mr. H. C Crawford, of Venango county, as follows:

"Our cows (not in full milk) are receiving about thirty pounds of ensilage and straw daily, and they are in better condition than any I see through the country, or my own when I fed twenty-five pounds of hay daily, costing twice as much. I can place a ton of silage in the silo ready for feeding (not including rent or fertilizing of land) for $1.30 per ton when I can grow ten tons per acre".

Commenting on the above statement, Mr. Ingham says:

'His ensilage cost him not quite two cents per day for each cow, and,—if we allow the same for straw consumed, the total cost would be less than four cents per day, not counting anything for interest on capital invested in land and cows, or labor of feeding and milking, and allowing nothing for value of manure. If Mr. Phelps and Mr. Crawford kept their cows as cheaply on pasture in the summer, as they did on ensilage in the winter, and their cows averaged no more than 150 pounds of butter each per annum, then their butter cost them less than ten cents per pound, charging the cows nothing for interest and labor, and crediting nothing for skim milk, buttermilk or manure.

If cows can be kept for less than four cents a day in winter, and pastured for the same in summer, while being made to produce 150 pounds of butter each, in Venango county, Pennsylvania, that is the place for every scrub dairyman to flee to with his cows, as there is no place in this state where it can be done; not with a herd of Mary Anns of St. Lambert, even.

But why write and print such rot. It is only a premium for scrub cows, scrub rations, scrub care, scrub dividends and scrub dairymen. C. W. JENNINGS.

Belleville, N. Y.

From Valley Mead Farm.

ED. HOARD'S DAIRYMAN:—Unquestionably the two greatest heifer calves of recent years were dropped at Valley Mead Farm, lately. One being out of Mechtchilde, 39 lbs. 10½ oz. of butter, seven days, the world's record of the breed. The other being out of Elgin Belle, 31 lbs. 9½ oz. of butter, seven days; 100 lbs. 6 oz. in 30 days. The sire of this champion bred and most beautiful pair is DeKol 2d's Alban, without any question the greatest living son of De Kol 2d, holder of world's four-year-old butter record, 33 lbs. 6 oz., seven days. Mechtchilde and Elgin Belle are still hearty cows, having that strong constitution, great capacity, and phenomenal milk machinery which the present day cows are lacking, to make 30 pounds butter a week. The heifer from Elgin Belle has already been engaged by O. M. Kellogg, of Cortland, N. York, at a tempting price.

Monticello, Wis. KARLEN CO.

Butter Making in Sweden.

One of Canada's strong competitors in the English butter market is Sweden. Special attention is given to improving the quality of the product, and every effort is being made to develop the export trade. The following, translated from one of Sweden's leading dairy papers, and describing some of the faults found in the butter made in that country, will prove of value as well as of interest to butter makers here:

RAW BUTTER.

Raw butter, we herein mean that butter which is made from raw or non-pasteurized cream. The demand for raw butter has considerably decreased within these latter years. In 1895 only 30 per cent of the Swedish butter factories made butter from pasteurized cream, while in 1896, 60 per cent pasteurized their cream, 25 per cent occasionally pasteurized, thus leaving only 15 per cent wholly engaged in the manufacture of raw butter. When the pasteurized and raw butter are compared the difference is most marked, the pasteurized being much finer and milder, hence the term "raw" for the coarser butter made from non-pasteurized cream.

COOKED FLAVOR BUTTER.

As the raw and coarse flavor in butter is objectionable, so on the other hand is a cooked or burnt flavor. All properly pasteurized butter must of necessity have a slightly boiled or scalded flavor, which is quite pleasant to the taste, this flavor being the test of its pasteurization, showing that it has been heated to the proper temperature. Butter made from properly pasteurized cream is a guarantee that you secure a well-keeping, fine-flavored article, absolutely free from bacteria. There is a difference of opinion as to what degree of heat the cream can stand, before reaching that objectionable flavor point. As during an exposure of the cream to, say, a temperature of 165° F. in an improper heater the butter can receive an objectionable or burnt flavor, which in a proper heater the cream can be heated to a temperature of 185° to 188° F., and result in a rich, finely-flavored butter. The benefit of a proper pasteurization of cream is thus seen, as all harmful bacteria, which induce disease are killed at a temperature of 185° F.

DOUGHY BUTTER.

This butter is not clear and does not melt readily and lusciously on the tongue, but lays heavily in the mouth like a piece of dough. Good, high-quality butter is more or less clear and readily salivated. The causes of the doughy nature of the butter are improper fodder to the cows, or too much buttermilk remaining in the butter. To prevent the doughy nature of the butter from the latter cause, never leave the butter longer than possible in the buttermilk. If the buttermilk is not immediately drawn, and the butter properly washed, the evil results inevitably follow.

TALLOWY BUTTER.

This butter has a greasy and shiny appearance, and if touched by the thumb or finger will receive the imprint of the lines on it. The taste of over-worked butter is tallowy, and the pores in the butter are filled with air instead of a clean, clear moisture. You can always find the faults of this in (1) over-churning or over-working, (2) churning at too high a temperature, or making butter from milk of stripped or nearly dry cows, (3) improperly ripened cream.

SOUR AND OVER RIPE BUTTER.

The causes of sour or over ripe butter are to be found in an improper "starter," too high a ripening temperature, or neglect to churn at the proper acidity stage. This butter usually contains too much water and casein, consequently the butter has not the keeping qualities of properly made butter.

MILDEW IN BUTTER.

Mildewed butter is partly caused by manufacturing or storing in badly ventilated or damp rooms. Mildew also arises through badly seasoned and improperly prepared boxes and parchment paper. The paper ought to be immersed in a strong solution of salt water for a period not less than ten hours before using.

GENERAL FAULTS.

These are innumerable, and start at the very commencement, from the milking of cows to the packing of the butter, but which should be avoided, in the interests of the industry and the community.

The Butter We Eat.

A Rockdale, Texas, correspondent of the Houston *Post*, who is in the dairy business, writes on the subject of the adulteration of butter which has been exposed by the analytical chemist of Michigan, recently referred to in an article in the states. The writer claims that as good butter can be made in Texas, without the employment of cold springs or ice, as in the East or West, and protests against the injustice of dairymen in that state being forced to compete with the villainous compound of which thousands of tons are annually imported. The following is an extract from the correspondence:

"There is no doubt as to the effect that would be produced by a perfect knowledge of what our legislators eat in their hotels and boarding houses under the name of butter. If oleomargarine or butterine, it is composed of tallow and everything greasy (whether filthy or not) about a slaughter or packing house. If "ladle stuff", which is butter, genuine butter, but listen: This butter is gathered from everywhere and anywhere. Buyers travel around in search of it, and find it in country stores, commission houses, and even in the cities. It has become rancid, filthy and entirely unfit for anything better than a low grade of soap grease, perfectly loaded with dangerous germs, flies, roaches, all manners of insects, and actually working with maggots; it's a horrible thing to think of, but it's true, nevertheless. This conglomeration is shipped to the refinery, laboratory or creamery (?) melted, skimmed and strained, colored, chemically treated, churned in fresh sweet milk, salted to the taste, packed in a nice fresh bucket and stenciled with some attractive brand.

"These goods come into our state every week in carload lots unchallenged. Families buy and use them, little suspecting their history; they call for, and pay for, butter, and very often, if not always, this is what they get. This may be denied by your grocer; would you expect him to acknowledge the fact, even if he knew?

The Farmer's National Congress.

The Farmer's National Congress will meet at Boston, Mass., Oct. 3, 4, 5 and 6. This is an important organization and every farmer should keep posted on the movements of this body, for it is advocating policies that should interest every tiller of the soil. Ex-Gov. W. D. Hoard, of Wisconsin, is President, and John M. Stahl, of Chicago, Ill., is Secretary.—*Coleman's Rural World.*

AYRSHIRES Finely Bred and from the very best families. Stock for sale, bred for milk and butter qualities. Also fine herd Chester White Swine. Correspondence solicited. FRED TSCHUDY & SON, Monroe, Wis

Dry Feed and Children's Milk.

ED. HOARD'S DAIRYMAN:—HOARD'S DAIRYMAN, Vol. XXX, No. 17, page 338, first column, last paragraph: "What is called children's milk is obtained from farms whose cattle have the whole year been fed on dry food."

Will you kindly inform me why this particular feeding is better for producing "children's milk?" A. M. H.

Shalam, N. M.

This is a survival of the day when doctors considered it absolutely necessary that only dry food should be used in the production of milk for the use of children.

Before the advent of the silo, and especially in cities and small towns, brewers' grains, distillery slop and other easily fermentable foods were used, and the poor results obtained from the want of cleanliness, and the use of the above foods, when they were not fit to be used, resulted in a poor quality of milk, frequently unfit for children's food.

Many of our doctors at the present time will not prescribe silage milk for children's use, insisting that the animals be given only dry feed. In spite of the prejudice of the doctors, the fact is that the finest and purest milk produced at the present time for children's and invalid's use, is produced by a liberal feeding of silage and concentrates.

The old prejudice will probably die hard, but the indications are, that with a better understanding of the relation of feed to milk production, the medical men will acknowledge the use of a succulent feed and give up their old dry feed for the production of children's milk theory.

Clean food and clean surroundings will produce clean milk fit for children or invalids. Dry food is not necessarily cleaner, and may be much poorer as a milk producer than silage.

Butter Test of Lassie of Dundee.

ED. HOARD'S DAIRYMAN:—I herewith send you a seven day test of the cow, Lassie of Dundee 94068, made in accordance with the rules of the American Jersey Cattle Club:

From April 14, 1899, to April 20, 1899, inclusive, she milked 282 pounds, 4 ounces of milk, which produced 18 pounds, 1 ounce of butter ready for the market.

During this test she was fed 28 pounds of bran, 28 pounds of oats and peas, 42 pounds of gluten meal, 14 pounds of oil meal, 18 pounds of hay and 40 pounds of roots.

Lassie of Dundee is an exceptionally fine cow, being of a dark brown color, and deep, well developed body, carrying a square, well placed udder, and is a cow for beauty as well as for business.

She was dropped Dec. 23, 1893; sire, Jersey Monarch 14084; dam, Girl of Linden 57487. M. H. OLIN.

Perry, N. Y. "Cold Spring Farm."

For the City Milk Trade.—Bottled Milk.

The first essential to success for the retail milk dairyman is to make better milk and give it better care, and get it to his customers in better condition than can be done by the citizen with one cow. This is true, especially in the smaller towns and cities, where a number of cows are kept by persons who expect to supply their neighbors.

First is quality and cleanliness. These two features will govern the output of a milk dairy more than anything else. The dairyman may think that his customers will not know the quality or character of his milk, but here he is mistaken. A few will not know. These few may be known by the faults they find, but the ones that really do know will say but very little about it but will buy their milk elsewhere as soon as possible. Quality can be made only by careful selection of cows that are healthy and rich milkers and by the best of care in feeding and caring for them. Feed only good, clean, sweet feed. Feed regularly. Handle them kindly. Milk regularly.

Next comes cleanliness. The cows must be clean, the stables must be clean, the milkers must be clean, all utensils must be clean.

Next is the method of getting this milk to the consumer in the best possible condition. We have sold milk out of a faucet can, an open can, with a long handled dipper, and pouring pail, and in bottles. We have no hesitancy in saying that if we were compelled to go back to the old faucet can we would go out of the retail milk business at once. Now, how to handle this milk in the best manner is the question. We will begin with the milking. The cow should be well fed, then her udder and teats cleaned; milk her as gently and quickly as possible. As soon as the milk is drawn, it should be taken to the dairy room, cooled and aerated at once and then put in bottles and sealed up air tight. If it is not sold at once these bottles full of milk should be immersed in water and ice until sold.

In our dairy we use a Champion cooler and aerator and an Ideal bottle filler. Here we can cool, air and fill twenty-four quarts in four minutes. We use the Commonsense bottles with waterproof pulp caps. Our cows are milked at 5 o'clock in the morning and 4 o'clock in the afternoon. We have help enough so that we can milk, cool, bottle and load the milk into the wagons in one hour. During the six warm months we deliver this milk twice per day and during the six cold months once per day. Considerable more is sold in the morning than in the evening.

Two wagons and two active young men deliver the milk to the customers in a little over two hours in the morning, and a little less than two hours in the evening. Our customers put their empty bottles where the driver can see them, and put a check in for the amount of milk wanted, and the driver changes a full bottle for the empty one. In this way we do not need to wait for a customer to come to the wagon, but can move along at a good pace.

What are the advantages of bottled milk? It is cleaner; can be done much quicker; gives every customer their proportion of cream; gives correct measure to everyone; saves much milk to the dairyman; does not break or whip the milk or churn it; it enables your customers to see at a glance, the character and quality of milk they are getting. It enables the dairyman to keep a system of checking that cannot be done when milk is sold out of can; milk will keep much better than when handled in cans; it preserves the delicious flavor of the milk.

Some of the disadvantages are, the first cost of bottles, etc., etc., the extra weight to be handled and hauled, the breakage of bottles, the cost of caps, the extra washing necessary to keep all bottles, etc. clean; the loss of bottles.

Some customers will use these bottles on their tables, instead of cream pitchers, others will use them for kerosene, coffee, molasses, pickle bottles, jam, jelly, catsup, etc., etc. In this way many bottles are lost and the utmost viligance is necessary to keep your bottles from disappearing in these ways.

We will mention a few outside points: Keep horses, harness, wagons and drivers clean and tidy. Be prompt, punctual and courteous. Be honest, truthful and firm. Do right, and insist on your rights. Be sure that you make as good milk as can be made, and if a customer is not satisfied with it, drop them out of your route without controversy. Invite your patrons to inspect your premises.

Keep your cows warm in winter, and cool in summer. Provide clean, fresh water for them all the time. Keep them from being tormented and worried by flies, by using Shoo-Fly once per day. Kill all strange dogs that come into your pastures or yards. Do not permit strangers in your stables at milking time. Use no soap about your dairy room; use salsoda instead.—CARL HUSSELMAN, *in Farmers' Guide.*

Feeding Dairy Cows and Milk Production.

Mr. Harold Faber, agricultural commissioner to the Danish Government, London, recently addressed the members of the Newcastle Farmers' Club, England, on "The Relation of Feeding of Dairy Cows to Milk Production."

Mr. Faber, in the course of his paper, said that if they wanted to find what was the influence on the milk production, of a certain change in the feeding, it was necessary that all the other influences should be eliminated. Many circumstances affected the milk production. If they wanted to find the relation of feeding to milk production, they must guarantee that the changes they observe in the milk production were really the result of changes in the feeding. There were many circumstances which made observation of changes in milk production, which were supposed to be due to change of feeding, of doubtful value in many cases. In order to eliminate all of the many disturbing factors that influence milk production, it was necessary to work on a broad basis. It was the system of Professor Fjord (on whose experiments the lecture was based) to take observations with many cows for a long time, on different farms, through different

seasons, and to work always with different sets of cows which were alike in every respect, so that the total weight, age, milk yield, number of days since calving, etc., were the same for each set of cows. As long as the feeding was the same for each set of cows, the milk production was also the same in every case. When a slight change was made in the feeding of one set, and a difference in the milk production of the different sets was observed, it was concluded that this difference was caused alone by the difference of feeding, and thereby some information was gained of the relation between the feeding and the milk production.

Having dealt in same detail with these experiments, Mr. Faber said the final result of these experiments, or rather of the exact observations taken on a large number of cows fed on practical farms in a practical manner, under ordinary working conditions, and for several months during two or three years, and comparing always two or more sets which were as nearly as possible identical, went to prove that, within the limits of feeding mentioned, the composition of the milk remained the same, whether an addition to the food was given in roots, or in corn and cake, or whether some of the corn and cake was replaced by roots. The same result, that the food, within practical limits, has next to no influence on the composition of the milk, has been found by later experiments. And this referred not only to the amount of fat in the milk, but equally to the amount other constituents. On the other hand it had been found that an addition to the food resulted in a larger yield of milk and a larger increase in the weight of the animals. The greater increase in weight was afterwards lost when the addition to the food ceased, and it seemed that the loss of flesh might partly reappear either as an increased flow of milk, or as a slightly raised percentage of fat in the milk, and the way in which it did appear seemed in some measure dependent on the kind and composition of the food given previously.—*Australian Pastoralist.*

English Milk and Butter Consumption.

In an able address recently delivered before the Bolton Dairy Farmers' Association of England, Mr J. B. Dowdall, one of the leading Manchester butter merchants, who, by-the-by, has had a wide experience in Ireland and upon the continent of Europe, stated some facts which should induce men to think who never thought before, upon the subject of which the lecturer treated.

Mr. Dowdall said that we were increasing our importation of milk at the rate of 4,000 tons per annum. If we assume that an average cow produces two tons of milk, although this is a little more than the average of the country, it means that the milk of 2,000 cows is annually required in excess of the requirements of the previous year, so that at this rate we shall soon employ the whole live stock of another nation to provide for our constantly increasing demands. Mr. Dowdall further calculated that we require annually, 10,000 tons of extra butter to feed our increasing population. We may take it that our annual consumption per capita is 15 pounds, or nearly four times as much as we consumed a quarter of a century ago. This means, if we assume that every pound of butter is produced from two and a half gallons of milk, that 25,000 tons of extra milk are annually required in this department alone, and upon the basis of our previous suggestion would necessitate the employment of a further 12,500 cows. As a matter of fact, it means that every year, from those two sources, as many cows are requisitioned to supply our extra requirements as exist in many of our English counties, such as Cambridge, Hertford, Huntingdon and Middlesex. These facts are, from one point of view, most lamentable. It is no doubt a matter of price which prevents English farmers keeping more dairy cattle and producing more butter and cheese, but there is something behind this explanation, which will continue to militate against our success in the dairy department, if we are not mistaken. The people of the countries from which we so largely import, are content—perhaps it is a case of *necessitas non habet leges*—with fewer domestic requirements and comforts. The Swiss dairy farmer, who supplies us with condensed milk and Gruyere cheese, has only to be interviewed, and his home life examined, to see how true it is that this is the case. In the Colonies the same facts hold good; men are compelled to live severer lives, and are content with modest clothing and the plainest of fare. In the Scandinavian countries the same argument applies. According to the Government consular report, the value of milk in Sweden is 4½d a gallon as against 5d. in England. We cannot absolutely accept either figure, although we have the advantage in price, perhaps a greater advantage than they suggest.

Clean Cans for City Milk Trade.

Boston, Mass., has put in force the following ordinance:

"No person in the city of Boston engaged in the business of producing milk for sale, and no person engaged in the business of storing or delivering milk in said city, shall store, cool or mix said milk in any room which is occupied by horses, cows or other animals. All rooms in which milk is stored, cooled or mixed shall be provided with tight walls and floors and kept constantly clean. The walls and floors of said rooms to be of such construction as to allow easy and thorough cleansing. The room or rooms aforesaid shall contain proper appliances for washing or sterilizing all utensils actually employed in the storage, sale or distribution of milk, and all such apparatus and utensils shall be washed with boiling water or sterilized by steam regularly after being so used."

The New England *Homestead* comments on the ordinance as follows:

"The greatest source of contagion and disease as afforded by the milk business as at present conducted, is the manner in which the cans are now handled. The peddler buys the milk from the contractor and may leave the cans at various private houses, stores, etc. On his next trip he collects the empty and dirty can, and sooner or later returns it to the contractor. Meanwhile the dirty can is exposed to all sorts of contamination, according to the place where it has been kept. This foul can is sent out by the contractor to the farmer, and the farmer receives it from 10 to 36 hours later, and has a terrible job to get it perfectly sweet and clean.

The language and intent of the new ordinance of the city of Boston is that this source of danger to the public health in that city shall be reduced by having the cans or other dairy apparatus and utensils washed by boiling water or sterilized by steam, regularly after being so used. This rule is not complied with by sending dirty cans back to the farmers, but the law can only be observed by compelling contractors to furnish clean cans, not only that, but this is the only way to protect public health, both in city and country from this possibility of contagion It is a question whether typhoid fever germs have not been carried from the city back to the farm in dirty cans.

"The farmers are willing to make good milk under sanitary conditions and to cooperate with the Board of Health of the city of Boston to this end, without, however, admitting that the Board has any constitutional power to enforce its rule outside of the city of Boston. But if the farmers thus co-operate, the least the city Board of Health can do is to properly enforce the law within the city limits and first of all oblige contractors to supply clean cans."

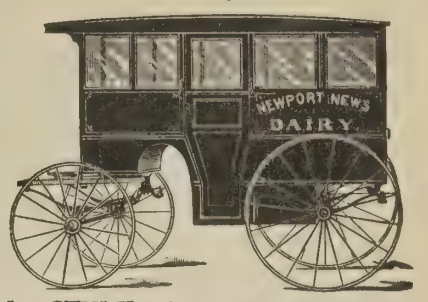
A Time For Noble Anger.

"This is a fact we have to know about our national life—that is ended as soon as it has lost the power of noble anger. When it paints over and apologizes for its pitiful criminalities, and endures its false weights and its adulterated food, dares not decide practically between good and evil, and can neither honor the one nor smite the other, but sneers at the good as though it were hidden evil, and consoles the evil with pious sympathy, and conserves it in the sugar of its leaden heart—the end is come."

Thus wrote John Ruskin thirty years ago The words seem prophetic as we consider the manner in which Gen. Miles' criticisms of unfit meat were received by a people so steeped in commercialism that they could not endure a whisper of criticism which might result in the loss of a dollar of trade, no matter how vile the stuff palmed off on our soldier boys gone out to meet death in support of the flag! And as we read the testimony before the Mason senatorial pure-food committee and the defense there made of the use of alum in baking powders and other harmful adulterations of foods, all of which are sold on the market as pure and at prices which should command the best, Ruskin's words rise up to warn us. And when we reflect upon the recent action of Illinois state legislature is giving time to the rascally frauds to dispose of their death-breeding adulterations, before putting into effect a pure-food law, we are compelled to ask if the end of this nation really has come—are we indeed so enslaved to the almighty dollar that the power of noble anger had departed?

Let us look fearlessly into the mirror thus held up, and dare to ask ourselves and answer with truth and soberness what these strange things portend in our national life. And let us as a people rise to smite the evil and honor the good and true, casting out the cheap john scallawags who hesitate at nothing if only they may add to their riches. We are painting over and apologizing for, not only small but large and menacing criminalities and are honoring the criminals, while we sneer at virtue and pass by honest poverty; we do endure, not only, but encourage, false weights and adulterations by taking for our social leaders the men who practice the frauds. The past year has brought to light a shameless condition of morals in high places in this country. A people who will be party to it need not complain when the inevitable results shall appear.—*Farmer's Voice.*

Hydraulic Separators.



The Iowa Dairy Commissioner sends the following to *Wallace's Farmer*:

The Dairy Commissioner directs me to give you some facts in regard to a test of the skim milk and cream from a so-called separator of the tin can variety, which test was made by myself and the milk inspector for the city of Des Moines. Possibly they will be of interest to your readers, especially as the water "power" used, is said, by the makers of the machine, to take out all the butter fat.

I was present when the agent put four gallons of milk and four gallons of water into his machine, and in exactly forty minutes he drew off seven gallons of skim milk and water, and then a gallon of cream. The cream and skim milk were tested, and found to contain 14 7% and 1.2% butter fat respectively. It will be noticed that the "skim milk" really contained four gallons of water and three gallons of skim milk, but the above per cent of 1.2 butter fat is the correct value of the fat in the skim milk, with the mixture of skim milk and water.

The agent, not being satisfied with the showing, set his milk over night and another can for an hour, and the test showed that the milk set over night still contained butter fat to the amount of seven-tenths per cent, and the milk set sixty minutes contained more than nine-tenths per cent butter fat. These amounts of butter fat, being respectively about one-fifth and one-fourth of the fat in the original milk, show a loss of 20 and 25% of the butter fat. Yet the dilution method is said to be gaining favor among the farmers of this state, and the sale of the machine is reported to be very large. You are at liberty to use these facts as you may desire. H R. WRIGHT, Clerk.

Aerating and Cooling of Milk.

Its Importance in Co-operative Work—Methods of Thorough Dairymen Disclosed.

Whenever advanced dairymen meet to discuss ways and means of improving their industry, at no point in their discussion is more enthusiasm displayed than when the airing and cooling of milk is receiving attention. The apparent reason for this anxiety is that much tainted and badly kept milk is received at the factories, and is the greatest of all sources of trouble to the cheese and butter maker. If nothing could be done to prevent such troubles as we speak of, it would indeed be a serious matter, as we find that even healthy cows in good pasture occasionally get food and drink that gives trouble in the milk when no means are taken to correct the faulty condition. It is to be deplored, however, that the milk received at the factories from farm dairies is not all from vigorous, well kept cows, that feed only from the finest pastures and drink only from the purest springs. Whether it be the provender the cow eats, the water with which she quenches her thirst, or the incorporation of odors in the milk after it is drawn, it is a fact that gaseous odors do get into the can, and when not eliminated give serious trouble to the makers of cheese and butter. The treatment for milk, that may have become contaminated from whatever source is, undoubtedly, aerating and cooling, which will not only enable the farmer to keep it sweet and fresh during the hottest summer nights, but it will largely do away with the troublesome condition of gassy curds. It has been estimated by no less an authority than J. H. Monrad, of Illinois, that if all milk brought to factories were aerated and cooled it would improve the quality of the butter one-fourth cent a pound and the cheese one-half cent a pound.

That milk should be aerated before cooling, we have no hesitation in claiming; for the reason that any taints, whether dormant or evident to the nasal organ, that exist in milk, when cooled are by the cooling process prevented from giving trouble after the heat is applied or the ripening stage is advanced. We therefore feel strongly convinced of the necessity of advocating aeration first and foremost, and would advise that it be adopted whetherthe milk is cooled or not.

There are several methods of aerating milk, which consists in subjecting it as much as possible to the purifying action of fresh air. This may be done by allowing the milk to escape through an aerator in small streams in the presence of pure air, or by forcing fresh air into and through the milk. The first method is performed by means of an ordinary tin pail thickly perforated, into which the newly drawn milk is poured and allowed to escape. The second by means of an inverted milk pan, thickly perforated, and with a handle attached. This is forced down through the milk in the can several times, the forced air escaping through the milk as it descends, carrying away any gases that may be contained in it, and oxidizing the milk at the same time. Another popular method of aerating milk is to pour it from pail to pail several times, at intervals of brief periods, or to bail it with a large dipper, so as to allow the access of air as far as possible. The following letters are from thorough dairymen, who are anxious to see our exportable dairy products command and maintain the highest place in the markets of Great Britian.

To have milk pure and sweet, all the feed and water that the cow gets should be pure and sweet. Her thighs, udder and teats should be clean on commencing to milk. The teats should be dampened—not wet—with clean water before beginning to milk. The first few streams of milk should be rejected. Every vessel that the milk is to come in contact with should be as nearly germ-free as elbow grease, scalding water and bright sunshine can make it. The milk should be strained as each cow is milked. Immediate and thorough aeration is necssary to cause the pure air of heaven to exchange places with the anything but heavenly-smelling gases generated within the cows body. Cooling after aeration depends upon the season and the use that is to be made of the milk. J. W. HART, Supt.

Kingston Dairy School.

In order to keep milk pure and sweet during the summer season we take care to cool and aerate the milk as soon as possible after it comes from the cow. The sooner the animal heat is removed the better. We set the milk can in a tub of cold water and strain the milk through a large strainer raised above the can, which allows the milk to pass through in small jets. In a short time we change the water in the tub, and take a pail with holes in the bottom and a stiff bail and push this down in the milk and then lift up quick and hold it above the can until the milk runs through; repeating the operation a few times until the milk is cooled and thoroughly aired. It is a good plan to have long coolers to fill with cold water to insert in the can. Keep the can out of the sun and away from bad odors. The cream should be kept from rising.

Oxford Co., Ont. D. LAWRENCE.

To make fine cheese or butter it is absolutely necessary to have clean, sweet milk. See that the cows, milk pails and cans are perfectly clean, also that the milker is clean. Immediately after milking, the milk should be removed to some clean place away from the barn or milking yard or anything that is likely to give off a bad odor. Strain the milk carefully, and as soon as possible after milking. Air well by dipping or pouring, or by the use of an areator; this should be attended to at all times, but especially during hot weather. Running the milk through an areator once is not sufficient, but should be repeated two or three times.

Never cool milk until it has been thoroughly aerated, because aerating tends to liberate taints, which, if not removed, become incorporated in the cooling and give trouble in the cheese or butter. For cheesemaking especially, it is very essential that all milk should be aerated. It improves the flavor and quality of the cheese, and requires less milk to make a pound of cheese. Milk keeps better in small quantities, and where the herd is not too large I would recommend the following: Have a pole supported at each end about four feet from the ground, and hang the milk pails along this on hooks, always having one empty pail; then commence pouring from one pail to another; continue this for some time, and you will have little or no difficulty in keeping the milk in fine condition. Good results are also obtained by using an aerator, through which the milk runs in very fine streams or thin sheets, allowing gases and animal odors to escape, and if milk is free from these, with ordinary care it will keep sweet and be in fine condition when delivered at the factory. In very hot weather it may be necessary to cool the milk by the use of water, but never do so until it has been thoroughly aired. When cooling with water, always leave the cover off the can and keep the milk stirred continuously. It has also been found that milk will keep sweet longer when cows have free access to salt. T. B. MILLAR,

Manager Thames Dairy Co., Middlesex, Co., Ont.

The care of milk should commence before the milk is taken from the cows, by seeing that they are in a healthy condition, that they have access only to pure, wholesome food, clean, pure water, and salt at all times. See that pails and cans are properly tinned and free from rust, and have been scalded and aired before using. Udders and flanks of cows should be wiped clean with a damp cloth before milking. Milking should be done in a clean place, by a clean person, with clean, dry hands. As soon as milk is drawn it should be removed to a clean place, free from barnyard, hog pen and other bad odors, and immediately strained and thoroughly aired by dipping or pouring. I would recommend the following method of airing milk: Provide pails enough to hold one milking; erect a pole about four feet from ground, covered with an A-shaped roof, made of inch boards, to protect from rain; fasten hooks in pole to hang pails on. As soon as milk is strained in pails, hang on the pole. Have one extra pail. Commence at one end of pole and pour milk from pail No. 1 into empty pail; No. 2 into No. 1, and so on across the row several times, back and forth, and leave in pails until morning The morning's milk should be treated in same way. JOHN BRODIE.

Elgin Co., Ont.

—Farmer's Advocate.

Dairymen Warned Against Preservaline.

The April bulletin of the Michigan Dairy and Food Commission contains the following warning:

We desire in this issue of the bulletin to caution dairymen and dealers in milk against the use in their products of the so-called preservatives now upon the market. In this connection we call attention to the following copy of a letter being mailed broadcast through Michigan, addressed to milk dealers in the various towns:

"My dear Sir—A mutual friend desires me to write you, as you have a large dairy and creamery. You know better than I, perhaps, the necessity of having pure milk for babies and for household use. Now, as a mother and possible customer of yours, I want to say a word about this. Many times I have been made nearly frantic by having milk spoil just when I needed it the most for baby. My doctor told me of a preparation made in New York which would keep the milk fresh and sweet till drank. It is called Preservaline and is harmless and cheap. I tried it and can vouch for it. I brought up my baby on milk in which Preservaline was used, and a healthier and plumper baby, for its age, would be hard to find.

"So, in the interest of myself and other mothers and housekeepers, I want to tell you about this. You can get this wonderful preservaline from the Preservaline Manufacturing Co., ————, or the branch houses in ————and——. If you mail them a postal order for two dollars, they will send you enough preservaline for five thousand quarts of milk or cream. Think how cheap this is and what a blessing it confers on you, also on mothers and housekeepers, for you can supply them with pure sweet milk or cream when needed at all times and in any kind of weather. I hope you will get a package and try it, for I know you will be as much benefited as I have been.

Faithfully yours,

MRS. KATE EGALETE.

"April, Eighteen hundred and ninety-nine."

The foregoing is a deceit and a fraud of the vilest kind. Masquerading under the assumed name of a woman, and clothing the counterfeited signature with the sacred mantle of American motherhood, this company seeks to promote the sale of its product in the very channel where its use will most imperil the health and lives of the children of our state. Can it be that the demands of commercial competition and love of gain warrant any human being to such despicable depth of deceit and falsehood? The use of acid preservatives in milk is dangerous, and we question whether a chemist of repute can be found in the United States who would countenance its use in milk for the feeding of infants.

We warn the milk dealers of the state,

WHO IS TO BLAME. Women as well as men are made miserable by kidney and bladder trouble. Dr. Kilmer's Swamp Root, the great kidney remedy, promptly cures. At druggists in fifty cent and dollar sizes. You may have a sample bottle by mail free, also pamphlet telling all about it and its wonderful cures.

ORDERS POUR IN FOR DEERING

"LIGHT DRAFT IDEALS" FROM ALL POINTS OF THE GLOBE.
The largest single factory of any kind in America is running day and night to supply the demand.
There is no important grain-growing country in the world where **Deering Harvesting Machines** are not in use.
The machines that have a reputation for steady, reliable work, light draft and great durability are everywhere sought after.
Deering pioneered and popularized roller and ball bearings in binders and mowers.
Deering machines are built to meet the practical needs of the harvest.
They are the kind that don't get out of order. They are easy on horseflesh.
That's why the nations of the earth unite in endorsing **Deering machines.**
DEERING HARVESTER CO., - Chicago, U. S. A.

MAKE ONLY SWEET ENSILAGE

Ever since the ensilage system has been introduced in this country it has been the ambition and effort of siloists to ***produce sweet ensilage.*** The making of sweet ensilage depends principally upon two things—***1st.*** the use of a well matured crop and ***2nd.*** upon low fermentation. Granting the maturity of the crop, shredded ensilage makes the sweetest ensilage. The reasons are, that shredded material is of a nature that makes it pack much more closely in the silo. That means exclusion of air; there can be no extreme fermentation and consequent development of acid without the free action of the air. ***Shredded ensilage possesses other advantages in addition to its sweetness:—*** it is eaten with great avidity by animals, being a long, soft substance and free from any sharp angles and corners to cut or lacerate the mouth and gums; it is therefore fed with less waste.
The best way to Shred Ensilage is with the
St. Albans Ensilage and Fodder Shredder.
It is the Original Shredding Machine and all other so-called shredders are merely imitations of this one. ***It will certainly pay you*** to look into the merits of this proposition and machine before buying. We mail free a pamphlet on the subject.
ST. ALBANS FOUNDRY CO., ST. ALBANS, VT.

many of whom in the past have used these preservatives, of the dangerous character of this practice. The department, through its dairy inspectors, will make a special effort this summer to detect the use of preservatives in milk sold for consumption, and we are determined that an arrest and prosecution will be made in each and every case found.

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—The offering of butter on Monday's Elgin Board of Trade aggregated 18,420 pounds. Bidding opened at 18 cents and all sales made were at that figure. The sales reported were as follows:

Factory.	*Pounds.*	*Price.*
Red Clover	4,500	18c.
Triumph	1,320	18c.
East Bu lington	600	18c.
Big Foot	3,000	18c.
Dundee	3,000	18c.
Total	12,420	

The sales for the corresponding week of the three preceding years were as follows:

June 27, '98, 24,360 lbs. of butter sold at 16 cts.
June 28,'97, 38,140 lbs. of butter sold at 14½cts.
June 29, '96, 48,480 lbs. of butter sold at 14½@15cts.

Elgin, Ill., June 26, '99. H. C. B.

Warning to Farmers.

(Press Bulletin.)

From numerous letters received at this station, it is evident that many farmers have been victimized by seed dealers, who have, unwittingly, furnished Bird Seed rape instead of Dwarf Essex rape seed for forage purposes.

Farmers raising rape for forage, sow the Dwarf Essex variety. This plant bears a thin, short stalk with large succulent leaves, which resemble, in appearance and taste, the leaves ot the rutabaga turnip. The plant grows about three feet high on good soil, with leaves spreading about the same distance.

Bird Seed rape is a smaller plant with a slim, tough stalk, bearing a few small leaves which are hairy on top, and yellow blossoms appear a few weeks after seeding. The Bird Seed variety resembles the wild mustard plant when in blossom. The true forage rape does not blossom or bear seed the same year it is sown.

If the farmer finds his rape field bearing plants resembling wild mustard, with yellow blossoms, he may be sure he has planted the wrong kind of seed, and should plow the field at once, sowing the Dwarf Essex variety at any time before the middle of July.

Fortunately the Bird Seed rape, which resembles wild mustard, will not spread or prove troublesome, as is the case with yellow mustard, so that there will be no harm except a loss of the crop. W. L. CARLYLE.
Prof. of Animal Husbandry.
Agricultural Exp. Sta., Madison, Wis.

WHAT NEXT?

Instead of taking a long time and letting the oily parts separate from their coverings in the natural way, the separator uses a strong friction to break the film, when the cream or fatty part is immediately separated, and being lighter, rises to the surface. Cream thus secured requires very little churning; the film being broken, there is practically nothing to do but to gather the butter and separate it from its butter milk, which consists mainly of a residuum of caseine and fibrine that cannot, at first, be wholly separated from the fat.—*Ex.*

It is strange what wonderful things are written for the education of the dairyman, and circulated as dairy (?) literature. The number of things about milk that are not so, and yet have been evolved from the inner consciousness of the writer under the pressure of necessity, would fill quite a book.

The above is a good illustration. It would be hard to get more incorrect statements into the same number of lines, yet we must congratulate the writer on his imagination. The spectacle of those fat globules rubbing against each other until the cover breaks, is very good. So also, is that "residuum of casine and fibrine, etc."

The 2-10000 per cent of fibrine that Dr. Babcock discovered in milk has had many strange properties attributed to it, and has been the cause of many cases of sick milk. We shall watch with interest the next role that fibrine is made to play in the handling of milk.

CONCERNING OUR ADVERTISERS.

Mr. C. A. SWEET, of Buffalo, N. Y., owner of one of the very best Jersey herds in America advertises for sale in the DAIRYMAN this week a St. Helier bull calf ready for service. There can be but one purchaser and he who delays will be the loser.

THE FLAG FOLLOWS TRADE.

Uncle Sam may now boast that "the sun never sets onthe American flag,"but the Stars and Stripes have but followed the achievments of the American inventor and mechanic. Years ago American harv sting machinery led the way and created a demand for itself in lands where "Old Glory" was never seen outside of books. Deering Harvesting Machines, made in Chicago, are sold today by the ship-load from New Zealand to Norway and from South Africa to Siberia, and in every land where grass and grain are harvested. The name of "Deering" is a household word the world over.

ED. HOARD'S DAIRYMAN:—The attention of dairymen and feeders, who own silos, or who expect to build them this season, is especially directed to the advertisement of the Harding Hummer Ensilage and Feed Cutter, shown in another column. This machine, while comparatively new to most of your readers, has been built for four years past, and is now in a state of perfection. It has the enthusiastic endorsement of all who have used it, among whom are a number of prominent dairymen, cattle breeders and feeders. It is considered a long step in advance of the old style cutters that use chain or belt carriers and renders silo filling the easiest part of the year's work by reason of its great capacity for cutting and storing in the most inexpensive manner. It simply cuts the feed into the best possible shape and then blows it at the rate of almost two miles a minute, through tubing of any reasonable length, up to 40 or 50 feet, into whatever place it is desired to store it.

The machine, while built especially for handling corn, green or dry, is well adapted for cutting other products, such as hay and straw, and if any dust is in the feed it will be separated in its passage through the machine and thus leave the feed clean and wholesome. The machine undoubtedly has great merit, and we advise our readers to investigate it. Address THE HARDING MANUFACTURING CO., Nashville, Tenn., for catalogue.

A very neat and servicable package fastener has been placed upon the market by H. B. J. Andrus, of Winooski, Wis. It is designed to meet the requirments of the butter and egg trade, and has no dangerous points, to harm and provoke those handling the package. There is small ad in this issue inviting those interested to send for circulars. Don't neglect to do so.

A unique subscription offer is being made by the Farmers Voice of Chicago. Marion Harland, whose Cook Book and other books are in hundreds of thousands of homes, has written a series of four new books on home topics,including"Health" ,,Home", "Household Management" and "Cooking". Each book contains nine chapters on as many different departmen ts. The books are not on sale at the bookstores, but the Farmers Voice has arranged to furnish them as a premium—the four books and The Voice to January 1900 for 50 cents. The books alone will retail at $1.00 for the set. The Farmers Voice is as progressive in its advertising as it is in agricultural journalism. Address FARMERS VOICE, 334 Dearborn St., Chicago, Ill.

VETERINARY.

Queries in this department answered by WM. HORNE, M. D. V. S., Janesville, Wis.

COW PHYSIC—Three-fourths to 1¼ pounds Epsom Salts (according to age and size of animals) and two ounces of best ground ginger. Pour over this three pints of boiling water. When at 105° F., give gradually as one dose.

MILK FAILING.—AN OBSCURE CASE.

We have now thirty-three head, thirteen just added to herd. We feed them on green pasture all winter, until April, when every thing begun to dry up. Then we had a ten-acre field of barley, which would not pay to cut, so we turned them on that. The second day five cows failed to give any milk, hardly. All had one or more quarters of their udder swelled and stringy material was milked out. One was giving eighteen to twenty-four pounds to a milking, but has never given more than three or four pounds since. She never had any stringy milk, but got very poor; is now due to calve in three and one half months. We are going to dry her up. The whole herd has been falling off ever since, and now three other cows are troubled the same way, one due to calve in a few days, which we have been unable to dry up entirely. We have been feeding fresh cut alfalfa hay, mostly cured as weather would permit, Kansas red bran, 8 pounds per day, one-third barley hay, and for two weeks a large handful of oil cake meal, and still they fall off, and the milk does not cream as it uusally does. The new cows added to the herd are falling off the same way. They are all in first-class condition, except the two that got poor, although they are picking up now. We gave the physic, as given in your paper, and are giving one teaspoonful of saltpetre once a day to the affected cows, but they remain about the same. One has been fresh only six weeks; gives a little milk out from two teats, and thick mattery material out of the other two. Her udder was swollen a good deal, and after two or three days her hind legs swelled up at the joints. She was taken about three weeks ago. The udder is the same, but the swelling has gone down. She never lost her appetite, but needed the physic. Shall we dry her up, or will she come all right again? Others have been milking some time, but are not due to calve until December or January. All the cows, new and old, are giving just one half their usual quantity. O. W. L.
Los Angeles, Cal.

ANSWER.

Yours is a singular and puzzling condition. In all my long, active, professional experience, I have never had anything like your case. Individuals do have all sorts of freaks and conditions, but a whole herd so affected is beyond my professional ken. That the cause is general, there can be not the slightest doubt. A close, continued observation, by one qualified, is the only hope of finding and removing the cause. Until this is found and removed you will be more than likely to be annoyed by a continuance. The difficulty seems to be failure to secrete milk. I would try a complete change of food, and also water, if you have any doubt of its purity. The nitre is good and can't do any harm. Intelligent, systematic physicking is always a good alterative, in man or beast. Accute inflammations and poverty being always a bar to its exhibition.

COWS WITH SORE FEET.

I have been troubled a good deal, this spring, with my cows' feet becoming sore between the two hoofs, and usually at the fore part of the foot. They have become very lame, sometimes being unable to use that foot at all. The trouble seems to start in the little pore which is between the hoofs on the front side. Have been using lard and red precipitate, but do not seem to be getting very good results from the same.
Three Oaks, Mich. E. K. W.

ANSWER.

Remove the cause at once; ninety-nine and a half cases of foul feet are the result of filth, the other half being over abundant extra growth of hoof; as above, remove the cause or you can't cure. Wash thoroughly with hottish water and tar soap. Then disinfect with Tilden's Bromo Chloralum, one to eight of cold water. Disinfect twice a day for a few days. Pyroligneous acid, 10 ounces, fish oil 30 ounces. Thoroughly mix and use once a day. Soak a piece of tow and crowd to the bottom, daily.

SCROFULA IN COW.

I have a cow which has five swellings extending from the point of the jaw to the mouth, and varying from the size of a hen's egg to about the size of a bean. All of these swellings are raw at the end, and discharge a sort of a thin watery substance.
Trenton, N. Y. R. L. M.

ANSWER.

You have a clear and positive case of malignant scrotula. I know of no form of doctoring to recommend, as the cow is disqualified as a breeder and milker; the milk is not wholesome and is not fit for use in any form. Any expense you may be subject to will be quite useless as the cow is not worth doctoring. This, of course, is my professional opinion conscientiously given, and the conclusion is with yourself.

THICK NECK IN CALVES.

What is the cause and cure of thick neck in calves at birth? As many as six in one herd, both sexes, grade Ayrshires. It is a loose growth along the wind pipe.
Dunbar, Ont.

ANSWER.

I know of no such a disease as thick neck. You have one general cause for this abnormal growth; may be the bull; may be farther away, but still it is in the blood, bred there by hereditary taint and will continue for all time to come, more than likely. If the swelling was at the throat you would have a clear case of goitre, or Debyshire neck. Look into the family record; find out the cause and remove it. If you can by outbreeding as far as possible.

INJURY TO TESTICLE.

I have a Jersey bull whose left testicle has been badly swollen for over a month. It is quite large and hard, but not very sore to the touch. Have rubbed with a preparation put up by a veterinary, also with hot vinegar and poulticed with flax meal. But it seems not to improve. Will it injure him to serve cows and will his service prove effective? He seems in good health otherwise. J. K. D.
No. St. Paul, Minn.

ANSWER.

You yourself tell what the matter is—enlarged testicle. The cause may be any sort of injury, or it may be of a spontaneous origin, likely is. If disposed, let him serve a cow or two a day, not more; over service does sometimes cause swelling of the testicle, but not as you describe your case. A few doses of salt will be quite likely to help his case. If he does not improve let me know, and I will prescribe for his case. Give him 7 grains of iodide of potassa for ten to thirty days, if needed.

BREACH OF CALF.

I have a very fine Jersey calf, five months old; have just discovered a breach near the naval; do not know the cause. Is there a cure? If not, would you advise keeping her for a cow? E. D. W.
Whitelaw, N. Y.

ANSWER.

Umbilical hernia is quite often permanently cured. But the true professional man is the only one to attempt the reduction. The operation is by no means a dangerous or difficult one in the hands of an expert. Umbilical hernia is usually the result of some defect or injury at birth.

FAILURE TO GET WITH CALF.

I have a cow that I cannot get with calf—calved one year ago. On examination I find the womb entirely grown closed.
Palmyra, Mo. G. V. S.

ANSWER.

You had no business to examine the os uteri. It is and should be closed always except at certain period. This foolhardy opening, as practiced by a very few now, has spoiled many of the finest cows ever seen upon this vast continent. I, with a few others, have been trying to vote it down for years, and have succeeded—only once in a great while practice this so-called opening. You do not say if the cow does or does not come in heat, so I can't advise you.

Horse Owners! Use

GOMBAULT'S
Caustic Balsam
A Safe Speedy and Positive Cure

The Safest, Best BLISTER ever used. Takes the place of all liniments for mild or severe action. Removes Bunches or Blemishes from Horses and Cattle. Same price and same quantity as above.

SAFETY HARD RUBBER MILK TUBES with hole in the end, and DILATING PLUGS
(Patent applied for.)

My Hard Rubber Tubes and Hard Rubber Dilating Plugs supplant all kinds of metal tubes. No blood poisoning or bruising. No dropping out of teat by its own weight. Two hard rubber tubes, 2 and 3 inches long, and two plugs $1.50 the four—and also one bistuary and two plugs $1.50 the three. By mail, the whole set $3.00. In writing for medicine, please say if the cow does or does not come in heat—as the medicines are as different as fire and water.
Dr. WM. HORNE, Janesville, Wis.

Production of Pure Cultures.

The cultures can be produced under several different methods, either by selecting milk from specially clean and healthy stock, or, better, by adopting the system of propagating from dry lactic ferment. This system being the cheapest, and also most reliable, is everywhere considered to be the best. The rules laid down by Blauenfeldt can, at any time, be followed with success, as the bacteria in this laboratory is selected under the supervision of an experienced bacteriologist. The dry cultures are, in this laboratory, sealed in bottles, and in this way carried all over the world.

Blauenfeldt's system is to procure 20 lbs. of pure skim milk—the milk must be pure and savory, and, by preference, skimmed by hand This is heated to a temperature of 178° F., and either kept at this for two hours or cooled at once and heated to same temperature again. After the heating, the milk is immediately cooled to 86° or 88° F., and the whole contents of a 1 lb. bottle are emptied into the milk under constant stirring. The mixture is then left to ripen, until it becomes equally thick and suitably soured. At this stage the milk has become fluid ferment, and when it has reached a state of a coherent mass, able to be detached from the sides of the vessel, it should at once be stirred and placed in ice or a cool room, where it may remain till wanted for use. During the period of ripening the temperature should, as far as possible, be kept even, which is obtained by placing the vessel containing the ferment in a vessel of water, maintaining all the time a temperature of 88° F. Another system for keeping the even temperature is to place the vessel containing the milk in a case, and place clean cotton waste or hay in the space between the sides of the case and the can. Where special appliances are not fitted this latter is the most suitable method to adopt. If the temperature is duly upheld, the ripening will be completed in about eighteen hours; although this may be at any time dependent on the regularity of the temperature.

The dry ferment or starters have now become, as beforesaid, the fluid ferment, and from this the culture is, the following day, obtained. A quantity of skim milk is taken, sufficient to form from one-tenth to one-twentieth part of the quantity of cream which has to be ripened by the cultures The percentage of ferment to be added depends on the time it is allowed to ripen, and, under ordinary circumstances, from 5% to 10%.

If fifty cans of cream, equal to 500 gallons, have to be ripened, one-tenth part of this is required for skim milk to be prepared for culture, which will be 50 gallons of milk. This milk is heated to a temperature similar to the first lot treated, and after cooled to 84° F., one gallon of ferment should be added to every ten gallons of skim milk. This should then be placed in a place where the temperature does not go below 84° F., and left undisturbed till ripened as previously described, which, in order to obtain a good and vigorous ferment, should be completed within six or seven hours. When ripened, the top layer, to the extent of about two inches, should be skimmed off each can, so as to prevent other bacteria, introduced from the air, from interfering with the pure culture. It also requires to be thoroughly stirred so as to make it quite uniform, similar to buttermilk, and free from cheesy lumps.

This ferment is now used for the cream, and should be added, as previously stated, in quantities of from 5 per cent to 10 per cent, according to temperature and time. Sufficient culture should be left in a cool place to propagate next morning's milk for culture. The propagation is carried out from day to day as long as the fluid ferment remains good. The frequency of the renewal of culture from the bottles greatly depends on the cleanliness and care shown in the factories, and also in the care taken in propagating and cooling fluid ferment. In most instances it requires to be renewed every second week. The most suitable temperature of the cream while ripening is from 67° to 72° F., but equally good results have been obtained by having it a little cooler, and adding more ferment and allowing more time.

The culture required is therefore set in the morning while separating is being carried out, and when these instructions are carefully followed in preparing same, should be ready to add to the cream about 3 or 4 o'clock in the afternoon. The cream should then be ready for churning next morning from 6 to 10 o'clock, according to temperature, percentage of ferment, and the general condition of cream

* *

The system of using buttermilk for cultures is also adopted by several factories in Denmark; but in such cases the renewal of ferment has to take place very often, and so makes it more expensive. It is also objectionable on account of the difficulties experienced in controlling the ripening of the cream and keeping the butter free from strange bacteria. According to Mr. H. L Russel's experience only a slight advantage is obtained in regard to keeping quality; and that as an effect, the grain of the butter is injured by pasturizing. This, however, is a mistake, as the butter gains considerably in grain and appearance if the pasteurizing is done properly; and as to keeping quality, we have only to refer to the cask of Danish butter exhibited to the Victorian factory managers at their last conference. Besides, there is a wide difference in the keeping quality required of American and that of Australian butter.—*Farm and Dairy* Australia.

Must Have One Policy.

Practical Men Concede the Worth of 10c Tax Plan.

In various dairy publications, I am sorry to say, I have read various bitter attacks on the policy pursued by the National Dairy Union. I have formed the impression, from reading these articles, that these sharp criticisms are not dictated by noble motives. They are not the result of conviction or an opinion formed. I fail to see any arguments advanced that will sustain the facts assumed by our opponents. The close reader cannot fail to observe the petty annoyance and the jealousy, putting it in plain words, that are the motives of these criticisms.

The policy pursued by the National Dairy Union is not the policy alone of its noble president, ex Governor Hoard, or the hard-working secretary, Chas. Y. Knight. It is a policy accepted among practical men. It is an accepted principle all over this country, where the individual rights of men are so large, that only through taxation laws, enforced by the federal government, can national evils be controlled.

Some of our eastern friends have certainly lost sight of the fact that every state dairy association that has met in convention since this movement commenced, including the National Creamery Buttermakers Association, has indorsed the efforts of the National Dairy Union to secure a 10c tax on colored oleomargarine.

In every radical movement we find friends, supporters and also opponents. The worst enemy of any movement is the fellow who stands off on the side, who criticises, ridicules and tears down, who seeks to destroy the effort of men who give their time and money to secure results beneficial to all; critics who give us nothing in return. We have no use for critics of this kind and I say to them, "If you are sincere, if you do not like our course, give us something else; give us some advice; start a movement of your own. Let us get the question thoroughly discussed. Let us all adopt the same policy. Let us stand united. If we do, we cannot be defeated. If next winter, when our cause comes up in congress, we stand divided, I predict that that alone will defeat this measure."

Now boys, let us take off our hats to the New York *Produce Review* and all other papers which, regardless of personal motives, come out in support of the National Dairy Union. We appreciate the efforts of Chas. Y. Knight, and his excellent paper. The New York *Produce Review*, and other papers, that have rallied to the support, stand fully as high in our appreciation and close to our hearts We appreciate, and shall always remember their conscientious motives—W. F. JENSEN, President Jensen Creamery Co., in *Chicago Produce*.

Mating.

The Male Is Not by Any Means the Whole Herd.

Many are satisfied with having a pure bred male of reputable pedigree at the head of the herd, regardless of whether his type and points of excellence are in harmony with the requirements of the herd or not, forgetting that defects that are common to both parents intensify themselves in the offspring, says *The Homestead*. Just what it is that at all points goes to make up the obscure thing known as "a good nick" would be difficult to define, but one of its elements undoubtedly is that weakness at certain points on one side of the house should be compensated for by strength in those particulars on the other. The facts involves a careful selection of the females in the breeding herd with a view of securing uniformity in them. For if they be widely at variance with respect to their physical conformation no sire can be chosen that will nick with them at all. If, however, the females of the herd be uniform, showing in a general way a similarity in their strong points and their weak ones, the sire to be used on the herd can then be selected with a view of correcting deficiencies, and to the extent that the uniformity prevails on the one side and the selection has been good on the other uniform results may be expected in all the offspring. In too many cases the purchaser of a sire relies upon somebody else's judgment to pick him a good one, the person intrusted with this duty, perhaps never having seen the herd on which such selection is to be used. If, however, the sire is chosen with special reference to the use that is to be made of him, outstanding defects can, to a large extent, be corrected, and by pursuing this policy for a series of generations great improvements can be effected. If the female herd is of one line of breeding through a series of years, the defects will be likely to be of one general type. Suppose, for example, they have too much length of leg, then a sire that is particularly low down will contribute to breed out the defect. Suppose there is a deficiency in the heart girth and consequently in vigor and constitution, then a sire having a large heart girth will measurably cure the difficulty in the offspring. If there is weakness in the flank, a male should be strong there. If the females are coarse and inclined to be rough, fining down can be accomplished by the use of a closely built, compact sire, and on the other hand, if the females are smooth, small boned, pretty and inclined to undersize, the selection should be made with a view of correcting these faults

Ropy Milk.

Cornell University has issued a bulletin on "Ropiness in Milk." The bulletin sums up the question as follows:

Ropiness is a fault of milk which does not necessarily depend for its cause upon the health of the cows. It is said to be caused by any one of several different species of bacteria. I have found Bacillus lactis viscosus to be the cause of viscid milk in two different creameries. In the two outbreaks investigated the trouble was found to be caused by the use of milk utensils which had not been sufficiently scalded. The bacteria remaining in cans which had previously contained viscid milk, were able to survive the washing and remain alive to infect new quantities of milk. Greater care in scalding utensils brought the trouble to an end. All small utensils were immersed in boiling water for three minutes, and the larger cans were filled to the brim with scalding water, which was allowed to remain for the same length of time. A thorough investigation of the sources from which the bacteria might have entered the milk at the stables, and of sources elsewhere, failed to reveal the presence of Bacillus lactis viscosus. Nevertheless there is reason to suspect that during warm weather these particular bacteria get into the milk from water.

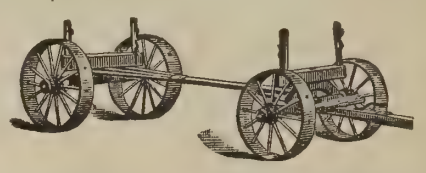
The importance of thorough scalding of vessels which have once contained ropy milk is urged upon the consumer as well as the dealer. Bacteria may readily be transferred from running water to milk by the agency of mud, which, drying upon the udder, may be dislodged during milking. Milk utensils which have been used for containing water, should be scalded before using again for milk. The apparent purity of water used about a creamery gives no assurance that it is free from bacteria.

"Go: You Are Free!"

If you were in prison and a good spirit suddenly opened the door and said "Go: You are free!" you wouldn't stop to ask whether the key that opened the door was the regulation pattern or not. If it opened the door, that is enough. Thousands of women who are sick and suffering might speedily be made strong and well again if it was not for an unreasonable prejudice against any but so-called "regulation" methods.

"Three years ago I was almost gone with womb trouble," says Mrs. Jennie J. Jackson, of Fergusson's Wharf, Isle of Wight Co., Va., in a letter to Dr. R. V. Pierce, of Buffalo, N. Y. "I tried many different medicines and got no better until I tried Dr. Pierce's medicines. The first bottle gave me ease. I have taken six bottles and I feel as well as ever in my life.

"My doctor did not have any faith in 'patent medicines' but he says '*something* has done you good.' I know if I had not taken Dr. Pierce's medicine I could not have lived long as I was nothing but a skeleton. I was so thin in flesh that it hurt me to lie down. Now I am well, and can work hard all day and do as much walking as I ever did, and sleep well all night. I can never be thankful enough for the good Dr. Pierce's medicines did me."



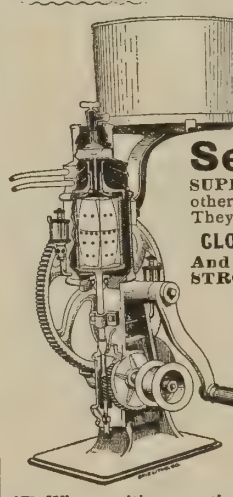
Dr. Pierce is a regular graduated and educated physician. He has had a more practical life-long experience with all forms of women's diseases than any other doctor in this country. His "Favorite Prescription" for female complaints is the most marvelously effective remedy for this purpose in the world.

Suffering women need not hesitate to write to him. All letters are held sacredly confidential and free advice will be sent by mail in plain sealed envelope.

Constipation is a little illness that if neglected builds a big one. Dr. Pierce's Pleasant Pellets cure constipation.

A Low Wagon at a Low Price.

In order to introduce their Low Metal Wheels with Wide Tires, the Empire Manufacturing Company, Quincy, Ill., have placed upon the market a Farmer's Handy Wagon, that is only 25 inches high, fitted with 24 and 30 inch wheels with 4-inch tire.



This Wagon is made of best material throughout, and really costs but a trifle more than a set of new wheels and fully guaranteed for one year. Catalogue giving a full description will be mailed upon application by the Empire Manufacturing Co., Quincy, Ill., who also will furnish metal wheels at low prices made any size and width of tire to fit any axle.

For catalogue illustrating Wagons and Bottled Milk Systems, address SHIPMAN, BRADT & CO., De Kalb, Illinois.

A Hand Separator

to be profitable must not only extract every particle of butter-fat from the milk, but must run so easily that it does not require the strength of a giant to turn it. We guarantee the

Empire Cream Separators

to run 50 per cent. easier than others of equal capacity. Their record for clean skimming is unequalled. We have the most complete line of hand separators in America; also power machines.

We have not space here to tell you why the **Empire** machines excel all others, but it's all in our catalogue. Send your address if you have one cow or one thousand.

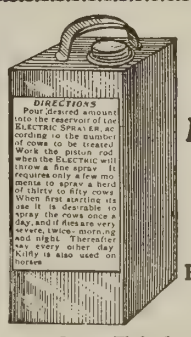
U. S. BUTTER EXTRACTOR CO., Newark, N. J.

THE NEW BOOK Feeds and Feeding

By Prof. W. A. HENRY, Wisconsin Experiment Station.

This book should be in the hands of every stock feeder in the country. Every reader of Hoard's Dairyman ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.



Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

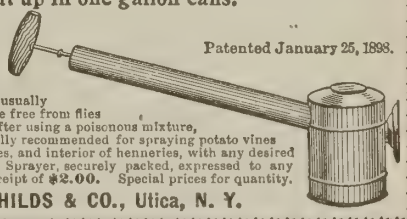
Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehensive from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be referred to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price, $2.00.

KILFLY.



More Milk, More Money, More Comfort for Cows and Milkmen.

A Liquid Mixture of Untold Value. Applied with Childs' Electric Sprayer.

Protects cows from the torture of flies, thereby increasing the amount of milk. Absolutely harmless to man or beast. Put up in one gallon cans.

Once Tried, Always Used.

ELECTRIC SPRAYER

Patented January 25, 1898.

Convenient and Practical in Every Particular.

Throws a very fine spray of any of the liquids and mixtures usually used for destroying insects, bugs, etc., and for keeping cattle free from flies during the summer weather. Can be thoroughly cleaned after using a poisonous mixture, which is conveniently done by removing the cover. Especially recommended for spraying potato vines with Paris green, also all kinds of plants, bushes, vines, trees, and interior of henneries, with any desired formula. Sample Lot—One gallon can KILFLY and one Sprayer, securely packed, expressed to any address (except in State of Maine) charges prepaid, upon receipt of $2.00. Special prices for quantity.

Agents Wanted Everywhere. CHAS. H. CHILDS & CO., Utica, N. Y.

WE ARE MANUFACTURERS OF HIGH GRADE DAIRY GOODS.
They are the strongest, the neatest and the most serviceable made in the United States. They are cheaper in the long run than the kind usually offered the people who only look at the price. When buying of your dealer see that they are of our manufacture.

CREAMERY SUPPLIES
We are making VATS colored, so as to show the natural grain of the wood. They are far handsomer and stronger than the old style. Give the creamery an air of neatness. We are agents for the
RENOWNED SHARPLES TUBULAR SEPARATORS.
If you intend building a new dairy house or creamery we will *furnish you plans free of cost.* We have a warehouse full of Churns, Butter Boxes, Elgin Butter Tubs, Elgin Babcock Tests, Tread Powers, Engines and Boilers. Send for illustrated catalogue and price lists or call at our factory.
HANEY-CAMPBELL CO., DUBUQUE, IOWA.

George E. Peoples.

Mr. Peoples is one of the noted creamery managers of the Pacific Coast. His butter scored highest at last seasons' National Butter Makers' Contest. He first showed the Pacific coast dairymen how to use Alfalfa milk and produce the finest flavored butter. He is an authority on creamery management.

BAKERFIELD, CAL., Apr. 2, 1899.

Mr. P. M. SHARPLES, West Chester, Pa.

Dear Sir:—I wish to say in regard to the 2500 lb. per hour Sharples Tubular Separator, put in for us the first of January, that it is giving entire satisfaction. After having used it fo three months, I must say that I am more than pleased with it. Having used nearly a l the leading separators, I formerly believed that there was none that could come up to the De Laval Alpha. But after using the **Wonderful Tubular,** and giving it a thorough trial, under almost all conditions, I think it has no equal. It is a great saver of oil and fuel, and produces a smoother and more churnable cream than any separator I have ever before seen.

To say that our patrons are pleased with the tubular, but lightly expresses it.

GEORGE E. PEOPLES,
Manager Bakerfield Creamery.

The Sharples Tubular Separator

SUPERB, SMOOTH CREAM.
GREATEST YIELD OF BUTTER.

No rubber rings—no metal bearings—no spindles—no complication—no danger—a hollow bowl—a simple bowl—a durable machine—all these and many other advantages.

New Zealand Ayrshires.

Some months since we noticed in a New Zealand dairy paper (*The New Zealand Dairyman*) an excellent picture of a typical Ayrshire cow. We wrote to the owner, Mr. James Gemmell, of Ormaru, N. Z., asking for some details regarding the animal, and he has kindly sent us a set of photographs from which the following cuts have been made.

Unfortunately he did not send any record of their butter production, so cannot give their record. The letter following shows how they are regarded by New Zealand judges, and we should be glad if breeders of Ayrshires in this country would give the DAIRYMAN their opinion of these animals as representatives of the Ayrshire breed. Following is the letter:

ED. HOARD'S DAIRYMAN:—I duly received your note *re* Ayrshire cow Saccharine, and now beg to apologize for being so long in replying to your request. At the time I received your letter we were very busy at harvest. And as you appear to take an interest in the Ayrshire breed of cattle, I thought it best to delay replying until I had time to develop a few photos which I thought might interest you and which you might turn to account. I exhibited the two last year at the Dunedin show, (Molly and Lady 2nd), Molly was first for cow in milk and champion of the yard, Lady 2nd took first for dry cow.

At the time Saccharine was taken she was newly calved and had been on short allowance for a week to guard against milk fever and had also been physicked, therefore, she was looking very empty and not at her best. However, I am sorry to say that she died within two days after with fever.

I exhibited also at Dunedin show in 1896, and with one exception took all the first prizes in the Ayrshire class. The exception being of the same blood as mine (bred from animals I sold). Lord Glasgow took the prize for bull and progeny, he entering the ring with all the first prize youngsters with one exception, following him. The exception being a 1-year-old bull out of a daughter of his, also bred by me. I mention this to show you the position the breed holds here in the show ring. Dunedin show is considered the best for Ayrshires in the Australian colonies.

AYRSHIRE COW, LADY II.

Property of JAMES GEMMELL, Ormaru, New Zealand.

AYRSHIRE COW, MOLLY.

Property of JAMES GEMMELL, Ormaru, New Zealand.

AYRSHIRE COW, SACCHARINE.

Property of JAMES GEMMELL, Ormaru, New Zealand.

GROUP OF AYRSHIRE CATTLE.

Property of JAMES GEMMELL, Ormaru, New Zealand.

You ask me for the pedigree of Saccharine?

She was sired by Prince of Wales, by White Prince, imported dam Princess Helena, by Premier, out of Old Violet g. d. Victoria, by Champion, imported g. g. d. Queen Mary, by Old Champion, bred by Gemmell g. g. g. d. Mary, by Young Jock, by Joy by Ayrshire Jockima g. g. g. g. d. Milkmaid, by Ayrshire Jock, imported g. g. g. g. g. d. by Burns Jock, imported, g. g. g. g. g. g. d. imported.

The whole of the sires and dams named were noted prize takers from Milkmaid upwards. Milkmaid was 14 years old before she was beaten in a show ring. She was bought by me over 30 years ago and all my herd have sprung from her. She, on one occasion, after calving, gave over 8 gallons of milk per day, in two milkings. Champion, imported, was never beaten in the old country but had to carry the second ticket when he met Champion (bred by me) out of Milkmaid in New Zealand. I bought Champion at auction for 170 guineas in Dunedin. Saccharine was considered the best Ayrshire cow in New Zealand, all the race have well shaped bags and good sized teats. I weighed Saccharine's milk on different occasions, after calving in 1896, and it went over 30 pounds at a milking, or say, from 60 to 65 pounds in a day, fed on grass alone. (Milk never tested for butter fat.) Molley is by Lord Glasgow; dam, Molly Darling, by Prince o Wales; g. d. Grace Darling, by Champion, imported g. g. d. Mary, by Jock, by Joy by Ayrshire Jock, imported g. g. g. d. Milkmaid, by Ayrshire Jock, imported Lady 2nd. Sire, Baron of Oxhill, imported; dam, Lady, by Premier, out of Old Violet g. d. Miss Gemmell, by Perfection, g. g. d. Dandy, by Champion, imported g. g g. d. Maggie, by Bobbie Burns g. g. g. g. d., by Bismark, out of Milkmaid. All prize takers. Baron of Oxhill was exhibited at the principal shows in New Zealand and never was beaten.

Ormaru, N. Z. JAMES GEMMELL.

WHEN our grandmothers put their milk pans outside the dairy room door, and let them stand in the full sunlight for hours, they were destroying bacteria just as effectively as if they knew what the little pest was, and the best way to get rid of him.

Now we know what the beast is, and all about him, but it is much to be feared that we are not taking advantage, as much as formerly, of the cleansing properties of sunshine. Throw open the blinds and let the bright sunlight into the dairy room. It will save lots of trouble with sick milk, and disgusted dairymen.

PERHAPS the best possible way for the farmer to rid himself of whey, so that it will not trouble him, is the underground whey tank. The tank, its surroundings and its product form a perfect remedy for an over supply of whey and incidentally a very practical combination by which to kill off any young or old pigs of which the farmer may have a surplus. Of course, the above may not come under the head of successful dairy methods but as an instrument for getting rid of both whey and young stock, the underground whey tank is an unqualified success and can be recommended as such to any dairyman who has a surplus of either article.

Transfers of Guernsey Cattle	422

Herbert B. Baldwin, chemist to the Newark, N. J., Board of Health, has found cases where the dairymen who sold milk put formaldehyde in it, then the wholesale dealer dosed it and the retail grocer doctored it again.

The Dairyman received a pleasant call recently from Mr. D. Raab, a noted dairyman, from South Pasadena, California. Although a man well on the shady side of life, Mr. Raab is as enthusiastic as any young man in the study of dairy problems. It is both refreshing and instructive to meet such men, and the editorial rooms of Hoard's Dairyman are always welcome to their calls.

The article "Embalming Milk," which appeared as an original editoral in Hoard's Dairyman of April 14th, page 167, has been quite extensively copied, and appears as original matter in the *Milk Reporter*, and other papers. The Elgin *Dairy Report* of May 8th, copies the same and credits it to the *Milk Reporter*.

When a paper steals matter in this way, it is pretty sure proof that the brains of the concern is named "scissors."

The *Country Gentleman* complains that the Dairyman clipped an article from their issue of June 1st and published it without giving credit to the *Country Gentleman*. The Dairyman takes every possible precaution to credit a clipping with the paper from which it was taken, believing that scissors and paste pot are but a poor substitute for brains.

We hereby tender the *Country Gentleman* an apology for the mistake.

That is a pregnant sentence E. C. Bennett uses on page 415, under the head of "Close Hits." Speaking of a "contented farmer" he says: He is satisfied because he has not learned how he is missing his opportunities."

Thousands of dairy farmers have written us saying, in effect, that the little investment they laid out in subscribing for the Dairyman, or in buying some book that looked farther into their own business than they had, was the means of adding to their wealth and pleasue in dairy farming, very greatly. It does not pay any man to be satisfied with poor results, when he can easily learn how to obtain better.

ANIMAL AND VEGETABLE PROTEIN.

Prof. Henry in his reply to H. B. C., of Menomonie, Wis., page 414, says:

"In some experiments at the New York Station, it has been shown that protein from animals is superior to protein from vegetable sources."

To our mind this is shown to be true by the way nearly all birds and animals, man included, feed their young for some time after birth. All food given to infant life is from an animal source. Birds, which subsist mainly on seeds, feed their young on worms and insects. The only exception to the rule we recall is the pigeon family, which use food for their young pre-digested in their own stomachs.

To a certain extent, these facts may be cited as an argument against a strictly vegetable diet for man. He does not commence life in that way.

FEEDING FAT INTO MILK.

There are still many farmers who believe that they can vary the per cent of fat in the milk of their cows by the kind of food they give them, while every thorough experiment that has been tried shows to the contrary.

These experiments show that we cannot take a cow, which naturally gives poor milk, and by feeding any special food, cause her to give rich milk. They also show that each cow is a law unto herself in this respect; that if we want rich milk we must seek for it in breeding. It is the cow, and not the feed, that determines the richness of the milk.

The *Milch Zeitung*, published in Germany, gives an account of an experiment, in which palm cake meal and rich cocoanut cake were fed, the object being to increase, if possible, the per cent of fat in the milk.

When a rich cocoanut cake was fed, there was a slight increase in the yield of fat, but it was accompanied by a decrease in the yield of milk, which more than counterbalanced the increase in the yield of fat. The conclusion arrived at, was that there was no advantage in feeding a ration richer in fat.

The same paper gives an account of an interesting experiment along the same lines at the Agricultural Academy at Pappilsdorf.

To a basal ration of hay, straw, malt sprouts, beets and grain, was added first linseed oil, then flax seed to increase the per cent of butter fat. The linseed oil caused a falling off in the appetites of all the cows, and they refused to eat the basal ration up clean. While on the linseed oil, the cows shrank in milk yield, but the milk yield increased when the flax seed was fed. The results of this experiment were considered entirely negative. The oil did not cause any noticeable increase in the fat in the milk, and it acted unfavorably upon the digestion, milk yield and general condition of the cows. The experiments along the same lines in Denmark have led the Danes to the following conclusions:

In the comparative feeding experiments with milch cows, now continued nine consecutive years, in which 2,500 cows divided into 218 lots, on twelve estates in different parts of the country, have been included, it has constantly been found that the changes, made in feeding the different lots, have been practically without effect upon the fat contents of the milk.

FIRST PRINCIPLES OF AGRICULTURE.

The Dairyman has received from the publishers a copy of a book on Agriculture with the above title, by Prof. E. B. Voorhees, director of the N. J. Experiment Station. The book describes, in clear and concise language, the various principles which underlie the science of agriculture. It discusses the soil, manure, crops, animal husbandry, breeding and feeding animals together with the products of the dairy. It is evident, as stated in the preface, that "no attempt has been made to cover the whole field of the various sciences in their relation to agriculture," but a very successful endeavor has been made to state the basic principles of agriculture in such a manner as to enable practical men to apply them in every day work.

We are more than pleased to see that the need for elementary books on agriculture is being met by men so well qualified for the purpose as Prof. Voorhees.

The need for such books is imperative, and the one before us is a most excellent beginning. It is published by Silver, Burdett & Co., Chicago.

EMBALMING MILK.

Salicylic Acid.

Salicylic acid has been, and is now, extensively used to preserve canned and bottled foods. It costs in large amount about 35 cents per pound and a pound will preserve a large amount of food products. It is used in milk, bottled beer, sauces, canned fruits and vegetables and according to the testimony before the pure food commission in Chicago, in almost all articles of food that are preserved in liquids.

It is made from that never ending storehouse of chemicals, coal tar. The direct source of its manufacture being carbolic acid. In the process of manufacture, certain by-products are formed, from which it cannot be completely purified, and these have a decided poisonous action on the human system.

The danger of this artificial salicylic acid is so great that doctors have, in many cases, forbidden the use of it as a medicine. Before the pure food commission, Dr. Pruyn Stringfield, of the Northwestern University Medical School, said:

"Its effect is to stimulate the action of the heart, and within a few minutes a depression of both the heart action and of respiration follows. I have had cases in this city where I believe death was directly traceable to the effect of salicylic acid drunk in beer. It is likely to paralyze the heart."

If an article is too poisonous to be used as a medicine, is it advisable to use it in our daily food?

Some doctors and professors, prejudiced in their judgment by a prospective witness fee, do not hesitate to proclaim it harmless in food, yet will not use it in sickness. Great is the power of the dollar! It will make a scientific man reverse his judgment quicker than an electric current can change its direction. In the meantime those of us who are compelled to take an unknown amount of such drugs daily, and are not being paid for the experiment, are much inclined to put up a decided protest. Also, we are going to continue the protest in the interest of our own drugged and dosed bodies, regardless of the condition, full or empty, of the pocket-books of the food mixer and adulterator.

MORE ABOUT FREEZINE.

A small circular of the Freezine Company has come to hand, and we have been much interested in reading of the wonderful properties of the article, as shown in the circular. It starts out as follows:

WHAT SOURS MILK.

"The souring of milk and cream is due to the action of minute organisms, known as bacteria. We have been experimenting with these bacteria in our laboratory for years, and have been rewarded by discovering a gas, which, when dissolved in a liquid, has the same effect on bacteria as *freezing them does*, and makes them *harmless*. This gas has no bad effects on milk or cream; in fact a chemist *could not find any trace of it if the milk were analyzed*, because the gas evaporates after it has done its work."

It is strange that they should experiment for years to discover what was already known, and concerning which there has been a large amount written in the last eight years.

The gas does make the bacteria harmless, but the process is one of poisoning, not freezing.

The claim that the chemist cannot find it in the milk, is liable to cause heavy fines to the milk man who puts any faith in the above statement and uses Freezine in consequence. Freezine is easily discovered by the chemist as certain Milwaukee milk men know to their cost.

"Freezine is perfectly harmless and is not injurious to the human system, as it freezes the bacteria and evaporates quickly, leaving the milk in a perfectly wholesome condition."

The above is absolutely false, as it does not freeze bacteria nor evaporate from the milk, and is, moreover, a decided poison.

Freezine is sold in quart bottles at $1.00 per bottle. It can be bought, wholesale, for 36 cents per quart. The absolute certainty of the manufacturer that Freezine is a good thing, is easily accounted for by the above prices.

HOW THE NEW HAMPSHIRE DAIRYMEN LOOK AT IT.

The dairymen of New Hamshire are, evidently, thoroughly aroused concerning the inundation of oleomargarine into that state, in an illegal form and color, and the almost criminal laxity which prevails in enforcing the law against illegal sale. They held a meeting at Concord, the state capital, on June the 20th, and it does one good to read the vigorous, independent way the farmers of the old Granite state took up the matter. We take from the New Hamshire *Monitor*, the following extracts from its report of the meeting. The meeting was called to order by N. J. Bachelder, Secretary of the State Board of Agriculture:

Mr. Bachelder called the meeting to order, and explained its purpose to ascertain the sentiment of consumers of dairy products, and of the general public in regard to the enforcement of the state law regarding the sale and use of imitation dairy products. He told of the failure of the Board of Agriculture to secure the conviction of the violators of the law, after their indictment by the grand jury, on account of the objection to "spotters."

Mr. Bachelder concluded by saying, if the dairymen of the state want the law enforced, the State Board of Agriculture will enforce it. He called for suggestions from those present, and invited Prof. Waterhouse, of Durham, president of the Granite State Dairymen's Association, to be the first speaker.

Prof. Waterhouse said it would be a good scheme to remove the beams from our own eyes, before going after the motes in our brothers. He alluded to the adulteration of dairy products, and gave details of recent ice-cream investigations, conducted by him. He insisted that a standard of dairy products should be established, and rigidly maintained. More care must be taken in butter production, or oleomargarine will "take the cake." Better dairy products must be made. The speaker said he could not agree with the principle of laws designed to benefit one class. If a man wanted to eat oleomargarine, he has a right to.

The speaker closed with the prophecy, that this season would witness a milk famine, and high prices of butter.

Charles Y. Knight, of Chicago, secretary of the National Dairy Union, was called upon and heartily greeted. He replied to Mr. Waterhouse, claiming that it was a question of fraud that must be fought, not one of quality. The courts will not prohibit the sale of oleomargarine, but they do prohibit the coloring of oleo to imitate butter. We only seek to legislate against fraud, and the color is the fraud.

W. K. Boardman, former Dairy and Food Commissioner of Iowa, spoke along similar lines. Consumers must be protected against oleomargarine. Take the color out of oleomargarine and it will sell for its true value, about ten cents a pound. Now the poor man is paying two prices for it on account of its color. The speaker told of the successful enforcement of the law in Iowa, where oleomargarine cannot be colored yellow or any shade of yellow. It has to be bleached and "white goods" will not sell.

E. M. Slayton, of Manchester, said: We are here to devise some way to say to the people of the state that we will not allow our law against the sale of oleo to be treated with the same disrespect as the law against the

sale of liquor. You people, most of you grangers, have influence with the politicians. You will be listened to. You represent one of the great producing interests of this state. Whatever you do here to-day will have weight with the grand jurors all over the state. We have got law enough here in New Hampshire. All we want is to enforce it.

Mr. Slayton's remarks aroused great enthusiasm and evidently struck home to the point.

Mr. Converse, of Lyme, was called upon and, in behalf of the 150 patrons of his creamery, said that their unanimous opinion is that the law must be enforced.

W. H. Sisson, of Cornish Flat, said: "Amen" to stopping the sale of oleo as creamery butter at two pounds for a quarter of a dollar. He knew oleo was sold in that way. We will put our butter at any standard required, but we do not want to compete with oleo.

Mr. Waterhouse, some of whose points had been warmly combatted by the previous speakers, explained his position further.

Mr. Cogswell, of Henniker, said his creamery had been doing business 10 or 12 years and its patrons are anxious to have this law enforced. If we can suppress the illegal sale of oleo gilt edged butter will profit thereby.

Mr. Stearns, of Winchester, Mr. Cowern, of Contoocook, and Mr. Gile, of Lebanon, had similiar opinions. Mr. Cowern had not found one farmer who did not favor the law.

Mr. Ash. of Lyman, had a paper signed by the farmers of his town asking for the enforcement of the law. He drew a rather sad picture of the condition of the farmers of the state, and Mr. Ellis confirmed his statements.

County Solicitor George F. Morris Esq., representing the Lisbon Creamery Company, brought up a new phase of the question, that of the prosecuting officer. He told of the difficulties experienced by such officers in the grand jury room and their inability to obtain indictments on "spotter" evidence.

You want to begin with the farmers, the men who are the most interested in this matter, and who form a large proportion of the grand jurors. Let every grange devote one meeting to this subject and educate their members as to the importance of enforcing this law. In the cities the wholesale grocers should take up the matter and prosecutions should be conducted through the regular police force.

Ex-Governor David H. Goodell, of Antrim, said: "This law, like every other law, should be enforced. Any law which pertains to the health and morals of the people, is difficult to enforce. The last legislature, however, took action to secure better juries. We should not be discouraged, but keep on doing our very best to secure the enforcement of the law. Let us be a law abiding people.

Upon reassembling, after dinner, vigorous speeches in favor of the enforcement of the law were made by Messrs. Moffett, of Lisbon, Ellsworth, of Meredith, Martin, of Lebanon, Wells, of Sugar Hill, West, of Chester, Wells and Simpson, of Deerfield, Morse, Fellows and Marshall, of Manchester.

The chair appointed as a committee to draft resolutions George F. Morris, Esq., of Lisbon, and Messrs. Sisson, of Cornish and Stearns, of Winchester.

Charles P. Hoyt, of Sandwich, said that the creamery in his town had to be given up on account of the low prices of butter, largely caused by the sale of oleomargarine.

The committee reported the following resolution, which was unanimously adopted:

At a meeting of delegates from creameries and milk producers throughout the state of New Hampshire, held at Concord, on the 20th day of June, 1899, it was

Resolved—That the secretary of the state board of agriculture, whose duty it is to enforce the oleomargarine law, request the govenor and council to call upon the attorney-general, county solicitors and chiefs of police of each of our cities and towns to enforce the state laws relating to the illegal sale of imitation butter and cheese.

Resolved—That the master of the State Grange be instructed to make the matter of the enforcement of the law a subject of discussion in all of the grange organizations of the state, and

Resolved—That it is the sense of this meeting that the proposed increase in the revenue tax on oleomargarine should be increased from two cents to ten cents per pound and we ask our representatives and senators in Congress to use all honorable efforts for the prompt passage of this law.

Mr. Knight, of Chicago, who spoke at the morning session, was called upon for a longer speech and told at some length of the work of the National Dairymen's Association and its fight against oleomargarine in its own home, Chicago. In spite of the numerous state laws against oleo, its production last year almost doubled, through the aggressive policy of its manufacturers.

There are but fourteen manufacturers of oleo in this country, but they are strong men, Armour, Swift, Hammond. The speaker gave startling statistics as to the output of oleo. In ten months Chicago sent out enough oleo to fill a train of cars fourteen miles long.

In looking about for a remedy we have hit upon the plan of increasing the internal revenue tax upon oleo. The farmers control their congressmen and they elect enough of them to put through any desired legislation.

Constant Access to Water.

A continental experiment in watering cows, shows that dairy cattle always in their stable, gave much better results when allowed constant access to water than when allowed a drink only twice a day. It was found that the milk yield increased, and no decrease of fat content occurred. The daily increase of milk was small, but, as estimated, it would improve the yield 40 gallons per cow per year. A noticeable feature of the experiment is that the cows drank a little less when permitted to drink at will than when furnished water twice a day. By drinking often there was less chilling of the stomach than where water had to be taken twice a day, and each time in large quantities. The digestion was improved, as with each small draught of water some gastric juice was secreted, which was not the case to the same extent where large draughts of cold water had to be taken.—*Farm & Home*, England.

Creamery Cesspools.

ED. HOARD'S DAIRYMAN:—Can you give me any information as to the use of cesspools for disposing of the creamery sewerage? Do they usually give satisfaction, and how should they be constructed? J. H.

Pilot Grove, Minn.

Unless great care is taken in the building, a cesspool will be the source of much trouble to the dairyman. As usually constructed, they are a hole in the ground near the factory, filled with stone and covered with boards. Into this hole, by an open drain, is lead all the drainings of the factory.

As the cesspool is dug without regard to the nature of the soil, it is usually filled with a putrefying mass, the source of many troubles to the dairyman, in the shape of gassy cheese and off-flavored butter. Unfortunately, drainage is the last thing considered in the erection of a factory, and a cheap makeshift is made to do the work.

If possible, the drainage should be discharged into running water, but, if this is not possible, see that the cesspool is put in a place some distance from the factory, the farther the better, and the drain connecting it with the factory is made of glazed tile with tight joints, so that it can be flushed and cleaned when necessary. The hole should be dug in gravel or coarse sand and filled with rough stone, so as to expose as much surface as possible to the action of the air.

If the cesspool is made in clay soil, there is no drainage and the hole soon overflows and forms a nuisance. Even in the best of soils, the sides of the cesspool will, after a time, become coated with a slime that will prevent the sewage from filtering into the soil, and it must be then either cleaned out or a new one dug.

The success of such drainage methods depends on the nature of the soil in which they are dug and the care which is taken of them.

This means care and some expense, but it is cheaper to supply the drainage than to lose several cents per pound on a batch of butter several times in the course of a year.

Judging the Cows.

ED. HOARD'S DAIRYMAN:—On page 370 you refer to us eight to one, as being mistaken. I do not understand the case. The question was, which is the better cow, and not which has given more milk and butter. The latter question enters into the calculation only so far as it indicates what they will probably do in the future. It being the duty of the cow to yield offspring as well as milk, and butter, their character also enters into the calculation.

Now as each has precisely the escutcheon that her form entitles her to, their forms are characteristic, and not artificially modified, and will be largely transmitted to their offspring. As eight out of nine prefer cows built on the plan of Rose, this fact adds materially to her value.

Regarding the past record of these young growing cows, it is probable that the smaller has matured earlier, and already reached her limit, while the larger is the coming cow.

As Gem has bred regularly, there is nothing remarkable about her records, except that they are remarkably good, and as I said in my first reply, the most creditable portion of her performance is in the first part of her period of lactation, for while she gave one-half more in one month than Rose, she gave only one-tenth more in the year.

If I understand correctly, Rose was farrow in 1896, that year being the latter half of a two-year period, and in 1897 there were only ly ten and one-half months between calves, thus shortening the period by six weeks and keeping her almost constantly pregnant. This would not only reduce her yield for that year, but would handicap her for the fore part of the next year. The latter part of the next year, she was favored somewhat by delayed pregnancy, but a bad send off cannot be fully recovered from.

Gem is a brilliant starter. She has made a great start in the beginning of her dairy work, and at the beginning of each lactation period, but Rose is a laster. She has the form of a laster, the escutcheon of a laster, and the records of a laster.

Milk vein development is a result rather than a cause of heavy milking, and is affected by each freshening. Gem has had two more calves than Rose; and a cow that milks very heavily for a comparatively short time will show greater development than one milking more evenly. For examples of this, compare the mammary veins of the two great Holstein cows, America, 97 pounds one day, 17,685 pounds one year, and Belle Sarcastic, 81.9 pounds one day, 21,075 pounds one year. W. C. HUNTINGTON.

Livingston Co., Mich.

BORAX IN MILK.

In case of adulteration tried recently, it was stated by an analyst that he had found no less than 30 grains of boracic acid in a pint of milk, and Dr. Stevenson, who was a witness, said that more than 10 grains of borax a day would be dangerous to a child, by retarding digestion, affecting the heart, and causing skin eruptions. It is presumed that the adulterated milk contained acid equal to 45 grains of borax, so that if a child had a pint of such milk per day, it would consume four-and-a-half times the quantity which, in Dr. Stevenson's opinion, can be taken without absolute danger. It is intolerable that men entirely ignorant of the strength of drugs and their effects should be allowed the uncontrolled use of them in food, sold to the public.—*Dairy World*, England.

Where is the limit to the use of such things? The dairyman doses the milk to keep it sweet on the way to the city; the city wholesaler puts in another lot so it won't spoil on his hands, and the retail dealer makes it still more certain with his remedy. What the result will be, depends on the preservative each one uses. In any case, the danger of the consumer getting an over dose, is very real. But so long as they have saved a little milk from spoiling, the effect on the consumer, infant or invalid, is, of course, a secondary consideration.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

FEEDING STANDARDS FOR MILCH COWS.

	DIGESTIBLE NUTRIENTS

23 to 28	2.0 to 2.5	12 to 15.0	0.5 to 0.8

FLY REPELLENTS

I have been hoping to see in your paper some formula for spraying on cattle to kill flies or keep them off and would be glad to hear from you or some of your subscribers, along this line through the "DAIRYMAN".

Quincy, Ill. H. W. S.

You will find two formulas for fly repellents on page 309 of the current volume, and in the last issue a correspondent writes that kerosene put on with a spray pump is very effective. The well known kerosene emulsion is also used to kill flies.

Much of the success with fly repellents, consists in destroying their breeding places. This is especially true with the horn fly that breeds in the droppings of the cattle. If these are covered up or destroyed, many flies are destroyed in embryo and the cattle saved from the plague of future swarms.

LINING FOR BUTTER TUBS.

What is the best for lining wooden kegs to ship butter to the West Indies? What do you think of parchment paper or paraffin wax? What are the objections to paraffin wax, and do you think it would melt?

Monction, N. B. G. R.

There is nothing better than a good quality of thick parchment paper, as a lining for a butter keg or firkin.

Paraffin wax is all right to coat the inside of the keg with and prevent the butter from taking up any flavor from the wood, but parchment paper must be put between the butter and the paraffin, otherwise the butter and paraffin unite and the butter sticks to the side of the keg. The same is true of wax.

CHEESE QUESTIONS—BLOODY MILK.

What causes the "floating curd," and a remedy?

What makes a cow give bloody milk? (The cow gives milk as if a tablespoonful of blood was stirred in a quart of milk). What treatment would you recommend?

What causes leaky cheese? What temperature to put cheese to press? H. M. P.

Kenoma, Mo.

When gassy curds occur it is an evidence that the lactic acid ferment has not developed in the proper manner, and that its place has been taken by gas forming bacteria. The easiest way out, if such milk can be taken in time, is to use sufficient of a good, clean starter which will give the proper ferment a sufficient start to overcome the gas producing bacteria. At the same time, if gassy milk is of common occurrence, we should very decidedly advise the use of the Wisconsin Curd Test, and thus locate the source of the poor milk. However, if the first indication of trouble you have is a floating curd, considerable can be done to improve the cheese, although not a first-class article can be made. When a floating curd is first noticed, cook a little higher and quicker, (sometimes as high as 110° F. may be necessary.)

Draw off the whey and pile the curd in one end of the vat; break up and stir with the hands, and then pile till the pin holes are flattened out. Repeat if necessary.

Bloody milk comes from some injury or inflammation of the udder. Good care and a thorough dose of physic will usually effect a cure.

If the cheese is not cooked enough, the whey that remains in the cheese will sour and cause "leaking".

Too much acid, or curd from which the fat runs, or a draft of dry air across the cheese will cause it to crack.

Put curd to press at between 80 and 85 degrees. If warmer, the fat is liable to run, and if colder, the cheese will not close up.

VALUE OF A MILK BUSINESS.

I would like to know, through your valuable journal, if the milk trade of any of the large cities in the United States are under the control of a syndicate.

What they paid for the right, or any information on the subject.

I send you clippings in reference to a syndicate proposing to buy out the milk route of Toronto. G. K. W.

Toronto, Can.

The proposed syndicates keep all such information very carefully to themselves.

The information contained in the clippings you send, is mostly newspaper wind. Syndicates have been proposed to take over and manage the milk business of nearly every large city of this country; but we cannot find any account of their doing any business as yet. Numerous large milk companies exist in the large cities, but their interests are not in common.

The value of a milk business depends so much on local conditions that it is impossible to give any estimate of its value.

Value of Breeds.

[A lecture by Prof. G. M. Gowell before the Camden Farmers' Insitute, Maine.]

We all start out as crop growers. That is the legitimate work of the farm, the growing of crops from the land and the selling of those crops wherever the most money can be procured for them. It has been the history of all countries, and particularly of New England, that when the land is cleared and made available for the production of crops, for a long period of years the crops are taken off, whether hay, or grain, or potatoes, and sold in these markets which will give to the producers the best returns, without reference to any future condition of the land.

Sooner or later every people have learned that the crops must be consumed on the lands where they are grown in order to maintain the fertility of those lands. There is no other known method by which we can maintain even our present condition, or improve upon it. However much we may object to any system of cattle feeding, we are forced to adopt some line of it. We cannot sell our crops and maintain our present condition, even.

There is a difference in the individual capacity of animals to digest and assimilate food, even though they are bred along the same line, to do the same kind of work. I shall not discuss the question whether we shall feed the hay or grain to dairy cattle for the production of butter or cream, or both, or whether we shall feed it to steers or to sheep. Dairying has become the leading agricultural industry in New England. We have grown into it because it was the better paying industry. But to some people the idea of dairying is not agreeable and they should seek for some other line of work, to which they think themselves better adapted.

We can adopt whatever line of work we feel inclined to, but having adopted it we must aim to have a class of animals that shall have the highest ability to return to us the greatest measure of the nutrients that are in the food. The majority of animals take out about one-fifth of the nutrients in the food and appropriate this to the building up of the carcass, the making of milk or the supplying of muscular energy. The other four-fifths is waste matter, which is voided as the solid or liquid excrements or through the pores of the skin or the exhalations from the lungs. This four-fifths we speak of as wasted, but it is not wasted; it goes back to the land.

Some animals have the ability to take out a much larger measure than others. Perhaps the average animal is capable of taking out seven dollars from each ton of hay. Some very excellent cows are able to take out, perhaps, ten dollars and leave it with the farmer, and we have other cows that will not take out more than four or five dollars, and some that do not leave much of anything for the farmer.

If our animals have good digestive and assimilative organs, that are able to prepare the food and store it up as beef, or milk, mutton, wool, or as muscular energy, they will return to us the highest price. Other animals, with more perfect organs, are able to do less perfect work, and other animals that are weak, lacking in constitution, hard fleshed, hard skinned, leave practically nothing for us; and so we go on year after year and waste much of our labor. I do not know of any line in which the farmer is so negligent as in this.

Now it is of no use for me to tell you how to improve your cattle unless I tell you the reasons for it. Our people are so constituted that they will not do anything unless they understand why they should do it and the way in which this work has been done. Our ancestors, back there in their savagery, in some way secured the first cow, that wild creature that was roaming in the woods, and somehow they milked her, probably they tied her to a stake. This was the first rude lesson the cow received in the process of civilization. Probably she was kept tied to the stake all night, and milked the next day. And so this work went on, the cow coming in touch with man, and man coming in touch with the cow, and the calf she produced coming in contact with the next generation, until the cow became domesticated, and became a co-worker with the farmer. By the aid of careful feeding, by the touch of the men who have had her in subjection, and by selection, this creature has been developed.

After 250 years of work by the English and American breeder, the ideal beef animal has been evolved and she has the ability to extract from the hay, the grains and the roots the largest amount of flesh and store it on her back. She is a flesh making machine; she can do nothing else well. That function has been so completely developed that the other tendencies have become almost completely obscured. She has the ability to place upon her back the food nutrients in the form of beef, but she has not her original abilty to give milk.

It is true that our Herefords, and many of our Short-horns, animals that represent most fully and successfully the type of the beef animal, have the faculty of beef production so fully developed that the function of milk production is almost entirely eliminated. The Englishman in doing his work, selected for his foundation stock the animals that had the thick form and rejected the animals that had the milking form. He selected animals that were thickest over the loins, widest over the rumps, that had the fullest chest, the greatest depth through the heart and shoulders, with short necks, and with round bones well covered.

The maker of the beef breeds early learned that animals that had the ability to make flesh had round bones. In placing your fingers on the body of this creature, it is with difficulty that you find the bones. You find her backbone in a little trench of flesh which comes up even with it; you cannot even discover the joints in it. Place your finger between her ribs, and you will find them near together. Wherever you feel you will find fine bones, covered with flesh. She has a fine chiseled head, and the edges of the ribs are well rounded. The legs are not flat as in the dairy type. The Englishman early learned that he wanted this type of a creature and he made her.

The external form of the creature reflects the ability of the animal to do its work. No cattle feeder will select a hard fleshed steer to feed for three, six or nine months, because he knows that a hard fleshed, hard, thick skinned creature is not thrifty. He seeks for creatures with soft flesh, that when pressed with the fingers will spring back, because in among these lean meat fibers is the water which he wants to replace with fat. He wants a sprightly flesh; and a skin that is thick and yet is soft.

While the Englishman was making the Short-horn cow, and the Dutchman was making the Holstein cow, right over on the island of Jersey they were making something that comes nearer to us, because the Jersey cow is the one we are at work with. You know all about the island of Jersey. It is five by eight miles in size, and the people have been at work there for all of these years, raising vegetables for the English market, particularly potatoes for the London market. You know how they have been doing that work on their naturally strong soil, where they can reach out and get the marine manures, raising potatoes by the trench system, and selling them in the English markets. You know about their small farms, only two or three acres in extent, very few containing seven acres, and each one of these farms supporting a family. They have done this for generations, and are doing it to-day.

Every one of these families had a cow, sometimes two or three of them, and these cows consumed the waste vegetables, the leaves and roots, and the little forage which they raised. There were no fences, they could not afford land for fences, and the cows were tied out to graze, and the women and the children cared for them, leading them out from the hovel each morning, carrying them a pail of water as they needed it, and bringing them back at night. A peg was driven into the ground, and the cow was tied to this and allowed to graze in the standing grass or forage, and after she had fed down all she could reach, the peg was moved a few inches farther, and so on across the field; then she was brought back to the place of beginning, to feed on the young grass that had grown since she first cropped it. The men did not care for the cows. It was the gentle touch of the women, it was the close contact with refinement that made the Jersey cow the sensitive creature she is. I doubt whether the touch of man would ever have done this.

You know very well that forty years ago the people in the state of Maine were engaged in growing steers for beef. We were growing oxen for the Brighton market, to furnish beef for New England. I know how it was in our home neighborhood. Every farm was selling from two to ten oxen each winter, fattened for beef. They had used the Short-horn and the Hereford, and have developed that type of an ox that we find no where else in the country, a cross-bred Hereford and Durham ox, and in this creature they were sending the produce of their farms to market. I do not know that we can do this to-day, but we have had to accept lower prices than they accepted when the Jerseys were first brought to this country. We had here, in Maine, one of the first importations of Jerseys. We were a ship building state. Our ship masters, touching for supplies on the Island of Jersey, early discovered that the Jersey people had a cow that was different from that found any where else. The cream and butter were yellower, the butter was firmer and better. And after a time a few of the creatures found their way here to Maine.

I remember, very well, when Major Howard, of Bath, brought home from Jersey, in one of his vessels, two heifers and a bull, and I remember how our neighbors discussed these creatures, these little Jerseys. They said, "We do not want those Jerseys; what are those little creatures going to do for us? We are growing beef. When we introduce those little creatures into our herds what kind of oxen shall we have? What do we want of them?"

The creatures were condemned, and these people were right, because beef growing was the specialty they were pursuing. They realized that the Jersey blood was so different from the beef blood that its introduction would ruin their work. But the Jerseys found their way on to the farms of Maine, a few in a place, as full-bloods and grades. They were treated in the same way in which the farmers were treating the beef creatures,—turned out into the yards in the cold, winter mornings, and fed on corn fodder or straw, which the farmer gave them before going into the woods, and perhaps they staid there until the boys got home from school, or until the farmer came home at night.

The little Jersey creature, thin skinned, thin haired, and nervous as she was, put out there and roistered around by those great beef steers, grew rather scrawney, and was rightly out of place. But in some way, our mothers got the idea that the milk from these little, diminutive creatures was different from the milk they got from their Short-horn cows.

The butter they made from it was a different kind of butter. They pleaded for the lives of these creatures, and they were given better shelter, better feed, and more gentle care, and from that they have developed into the grand dairy stock which we have in our state to-day. And I feel free in saying, from a close observation, that no state in the country has a better foundation for carrying on this great work of ours, than we have in our grade and pure bred Jerseys. They have developed into what they are.

But there is something required besides the Jersey blood, in the animal with which we shall do our dairy work. When these Jerseys came to the state we awoke to the fact that dairying was going to be the leading line of work. When the price of beef went down and the price of butter went up, every dairyman sought to possess Jersey cows. That was all that seemed to be required,—that his stock be Jersey. Our people realized that the milk of the Jersey cow, and the butter made from it, were different from the milk and butter of any other breeds. People outside got a taste of the butter, and there was a greater demand. The dairy interest has become a prominent one from Maine to Minnesota, and yet, with this wonderful increase in dairying we are not making more butter than our people are eating, we are just beginning to export. The consumption has so increased that the demand has increased with the increase in dairying, and we are not yet able to overstock the market. The dairy cow is yet able to give us more for the food she eats than is the beef steer, or any other class of animals.

We have begun to make some investigations regarding the receipts of farmers during the last few years, particularly with reference to our dairy concerns, and we have found by asking the creamery operators to return to us the number of farmers furnishing them cream and the amount of money paid to their patrons, that out of 60 creameries one has returned $60 as the amount paid for each cow furnishing milk or cream for the year. This was a large return, it was exceptional. A few creameries have paid the farmers $50 per cow, an average for all the cows furnishing milk or cream for the year; quite a number have paid $40, a good many $30, and some as low as $20. What is the matter?

We realized that we wanted the Jersey cow, because only through the Jersey and Guernsey could we get butter of this high quality sufficient to supply this great demand that has been created, and sufficiently good to give us the high price we desired. So anxious were we to develop our work, so anxious was everybody to engage in it, that every heifer calf has been raised.

We have not pursued the course that the Englishman, the Dutchman and the Jerseyman pursued. We have not selected the best and rejected the poorest, but we have gone on and raised every heifer calf from the first. I do not think that I have ever known of a breeder killing a Jersey heifer because it was not good enough to raise. We have raised the good ones, and we have raised the poor ones. The good ones have given us the high returns. The poor ones are largely responsible for the low prices we are receiving for our hay and grain when fed.

I want to illustrate this: In this cow on the chart, we have the Jersey Belle of Scituate, a good cow, not the best. She made, for five months, nineteen pounds of butter a week.

"The Prudent Man Setteth His House in Order."

Your human tenement should be given even more careful attention than the house you live in. Set it in order by thoroughly renovating your whole system through blood made pure by taking Hood's Sarsaparilla. Then every organ will act promptly and regularly.

Hood's Sarsaparilla
Never Disappoints

The American
PACKAGE FASTENER.

Perhaps you never saw it. A Fastener **entirely new**; suitable for all creamery packages, egg cases, and all light boxes. Patented May 2, 1899. Send for circulars and samples.
H. B. J. ANDRUS, Sole Manufacturer,
Winooski, Wis., U. S. A.

Not a Preservative

but a preventive. If you would have your milk keep sweet longer and be free from all objectionable odors, use a CHAMPION Milk Cooler-Aerator. It does its work perfectly and it's use does'nt violate any law—it doesn't need to be used on the sly. Our book "Milk" is free.

CHAMPION MILK COOLER CO.,
67 Main Street, - Cortland, N. Y.

We have others that have given us more, but we have none that illustrates better than she what a good cow is. Let us look at her form. You will notice that her fore quarters are much lighter than her hind quarters, that she has no great depth in the shoulders. You find that she has an immense depth through the loins, through the flank; she has an immense development of the hind quarter; she is broad over the loins, broad over the rump.

That great depth there gives a chance for storage of large organs of milk production and reproduction. Notice her neck. It is not a fine, narrow neck; it is not the rounded neck of the beef type, but it is a neck somewhat wide on top and widening down to the neck vein. Notice the head, the dished face, the great depth of jowl, the great depth across the eyes, the length of the face from the eyes to the muzzle.

She has a large barrel where she can carry large quantities of food; a large udder, long lines of connection with the body, in front, behind and up the sides; a great laboratory where she manufactures the blood into milk. Notice the upheadedness, the courage, the strength. She gives evidences that she has the ability to work. That is the kind of a creature we should aim to produce.

Some on said the other day: "That is the kind of cow the farmer can just as well have as not; and why don't they all have that kind?" That is all nonsense. We shall not live to see all the cows brought up to that standard. We shall not live long enough to perfect all cows perfect as she is perfected. But we can *make* some improvement.

I now wish to call attention to the other cow on the chart. She is a thoroughbred Jersey, registered in the American Jersey Cattle Club. She makes yellow butter, firm butter; but she shows at once to you that she is lacking in physical capacity. She is lackin in strength, she is lacking in the ability to perform. She is peaked behind and in front, narrow at the chest, long and thin in the neck, narrow through the heart, with small contracted lungs. I said that we wanted a long neck in the dairy animal and a short neck in the beef animal. This is true, but we do not want the neck too long. This neck is long and thin; it is not connected closely with the skull, which indicates weakness. The head is long and the jowl narrow across the base. She is narrow over the loins, her organs of reproduction and milk production are restricted. She has a small barrel, her thighs are near together, and she has a comparatively small udder, with a short line of attachment in front, and teats close together. Her legs are too small and fine. She shows us that she has not the ability to work.

The well-made dairy cow, the cow through which the farmers of Maine are to market their produce, should be a creature that will eat a reasonable quantity of food and assimilate it, and continue to do that work for a great length of time. We give our cows about twenty pounds of hay and about five to ten pounds of grain, with silage and roots, and we expect a cow of the type of Jersey Belle of Scituate to do work, and give us good blood and milk for a dozen or fifteen years. She is strongly made; she does it and will do it.

But if you attempt to give this other animal the normal ration, for a time she will consume it, but after awhile you find part of the hay or grain left in the manger. She has rejected it, she is "off her feed," you say. I know nothing more annoying than this. She does not take it because she has not the power to eat, digest and assimilate it. You find her udder out of condition, you find one quarter of it inactive. It is very annoying to try to run this weak machine. And after you have coddled her and nursed her along all this time, you find that she has only given you a small price, per ton, for the hay you tried to market through her.

Now had the weak calves been rejected, we should not have had so many weak cows, but cows of a higher quality.

I wonder if you have thought what this matter of constitution means? We must have it in our beef type. We carry the beef animal only from two to four years, but we expect that creature to stand high feeding that length of time, and must have a strong constitution. It is not something that is fed into an animal, or that is put into her by care; it is born into the animal. This cow (Jersey Belle of Scituate) was born with a strong constitution; but this other animal, no matter how good care she might have had, would never have developed, because she was born a weakling.

The matter of cross breeding is constantly coming up for discussion. Some one will say, "what do you think about crossing my Jersey cows with Holsteins?" I want to get a little more milk than the Jersey cow is giving, and I think I could cross her with a Holstein." Or, just now, the question might be in regard to the Short-horn. There is a call all around for an animal that will grow good steers, and give a large quantity of milk, and the people that attempt to combine beef breed and the milking breeds, are not going to be satisfied, unless they get a cow that will give all the milk possible, for a cow to give, and make the best beef, and all the beef possible. They expect to get a cross that will do all the work in both directions. But can we take the beef and the milking breeds, and cross them to advantage?

This creature that produces milk, has been bred for that for 200 years. She has been bred not to make flesh. The beef animal has been bred to make beef for all these years and do nothing else. The ability to make milk has been almost entirely eliminated. Now you are proposing to take these two creatures, whose tendencies are just opposite, and produce a cow in which you will unite them. You want to combine the qualities of those two creatures, and get an animal just half way between. You cannot do it, but we will suppose you could. What is going to be the result?

The Jersey has the ability to get the greatest number of dollars out of the hay you give her, in the form of butter. The Short-horn has the ability to get the greatest number of dollars in the form of beef. When you put them together you make an imperfect creature. You have introduced into the beef creature the milk producing tendency, and it cannot make beef to advantage.

On the other hand, it cannot make milk to advantage, because you have introduced the tendency to flesh production. When you feed the cow for beef, she will make more milk; she is annoying you because she is putting it into milk. When you feed her to make milk, instead of giving more milk she fattens up, and is unsatisfactory.

There is so much antagonism between blood elements, that are dissimilar and unrelated, that they do not unite well and evenly. They are apt to diverge. It is the hardest thing in the world to get two animals of opposite tendencies to unite their blood elements. You cannot have them divided just evenly. They are apt to side over towards the dairy animal, and give you dairy animals with beef indications but slightly developed, and with milking organs impaired, or they will go towards the beef animal, and give you an inferior beef animal with small tendencies to produce milk. I would not cross breed.

I certainly would object to throwing away the work that has been done. What does it mean when you take your pure bred Holstein, and your pure bred beef animal, and breed them together? You throw away 200 years of work that has been done in one direction, and propose to start over. This work is too valuable, life is too short for us to ignore it. We have animals that are good enough in any of the breeds, and our work is by selection, care and handling to make these breeds better. Take cows like Jersey Bell of Scituate, or the Holstein cow Aaggie, and make selections, and keep within the breed, watching where you can select and make the best of them.

Skim Milk for Calves.

Many points will have to be briefly noticed to understand the essential changes that take place from the time the milk is drawn from the cow until the cream is separated from it. Separator skim milk makes the best feed for any growing animal, outside of the whole milk, and we are nearly convinced that after the young animal is a week or two old and the skim milk is fed warm, with the animal heat still in it, it gives equally as good results as the whole milk, especially where a small quantity of oil meal is fed in it. I want to be understood that it is only where the milk is separated directly from the cow, with all the animal heat yet in it, that such results are to be secured. Where the animal heat is allowed to escape and the milk is reheated, a large per cent of its value as a feed has left it. Of course, none of its elemental value has left it, yet we regard the animal heat, with its gases still in it, of essential worth and of great importance in digestive value. When cold and reheated the animal must necessarily furnish the gases, before digestion can begin, hence calves do not grow with the vigor and healthful degree of rapidity that they do on the fresh, warm skim milk.

The next best class of skim milk comes through the deep setting process of Cooley system, where the separation occurs, when submerged in cold or ice-water, taking from 12 to 24 hours. The skim milk is always in its greatest purity when kept cold, and will keep fresh longer after drawn from the cans, to be reheated, than by any other process we know of. Yet the same difficulty must be met in the reheating of this milk as in cold separator milk, though we have secured fair results from the deep setting plan.

Then comes the creamery separator milk, which we have never felt like praising very highly during summer months. Too many opportunities are afforded milk, taken to creameries but once each day, to become inoculated with the most undesirable kinds of fermentive bacteria, which greatly injures the feeding value of it when returned to the farmer. The reheating process, especially of the evening's milking, starts bacterial activity which carries the same process into the morning's milk, resulting in the souring of the whole mass, or if not entirely sour, brings it to that point when again reheated, and causes the cheesy separation that Mr. Porter mentions, which is so undesirable.

We have tried sterilizing the skim milk at the factory, but frequently found that overheating produced a separation of the curd and whey, making it unfit for calves; consequently we had to go back to using the Cooley and sending nearly pure cream to the factory so as to have skim milk fit for our calves.

Our experience is that summer skim milk from the factory is not fit for calves, at least after the morning's feed. When we have used our own skim milk from the Cooley we never have any trouble from the disease. We are sure that continued use of factory milk will vitiate any calf's stomach and destroy proper digestion.

In conclusion we would encourage Mr. Porter and any others similarly situated, to purchase a separator and feed the skim milk direct from the separation and place the cream at the factory as per butter fat test. On the other hand we see that there is profit in the departure, from the saving of butter fat over the processes of separation and nearly the doubling of feeding value from the skim milk. We appreciate the fact that separators are expensive, but they have come to stay; their increased use is apparent on every side, and they will continue to increase as farmers come to realize their advantage — GEO. E. SCOTT, in *Ohio Farmer*.

BACTERIA, in one sense, resembles a mortgage, they work day and night but not always for the farmer's benefit. They are just as likely to pile up interest against him as for him and will do so unless he has made suitable provison beforehand to destroy his enemies and keep hisfriends under control.

BILIOUSNESS

Do you get up with a headache?
Is there a bad taste in your mouth?
Then you have a poor appetite and a weak digestion. You are frequently dizzy, always feel dull and drowsy. You have cold hands and feet. You get but little benefit from your food. You have no ambition to work and the sharp pains of neuralgia dart through your body.
What is the cause of all this trouble?
Constipated bowels.

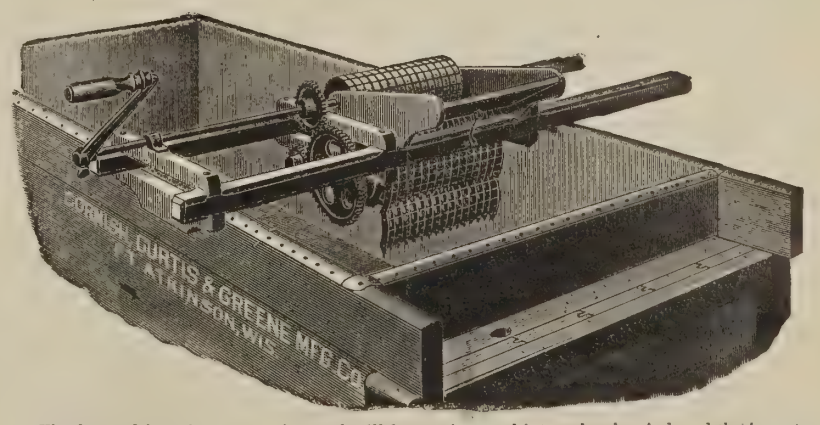
Ayer's PILLS

will give you prompt relief and certain cure.

Keep Your Blood Pure.

If you have neglected your case a long time, you had better take

Ayer's Sarsaparilla



also. It will remove all impurities that have been accumulating in your blood and will greatly strengthen your nerves.

Write the Doctor.

There may be something about your case you do not quite understand. Write the doctor freely: tell him how you are suffering. You will promptly receive the best medical advice. Address,
Dr. J. C. Ayer, Lowell, Mass.

PIGS Eligible to REGISTRY, and First Class Stock, at Reduced Prices. Chester White, Berkshire, Poland-China and J. Reds. Thoroughbred and Grade Guernseys. Also Poultry. W. B. HARVEY, West Grove, Pa.

Kasper Rotary Curd Mill.

The demand for a large capacity curd mill for cutting curd into cubes has induced the inventor to bring out the Kasper Mill. In construction the mill consists of a rotary cylinder made of knives in the form of cubes. Against these knives a wooden roll revolves with indentation to fit the knives of the cylinder; the curd being fed into the hopper is forced through the openings in the cylinder by the wooden roll. The cylinder is made in three sections hung on hinges, and, as it revolves, each section as it comes to the lower part of the cylinder, opens and allows the curd to drop into the vat, the section closing again as the cylinder revolves.

It is estimated that the curd from 7,000 lbs. of milk can be cut in from 7 to 10 minutes. The mill operates easily, being light running and adjustable to either hand or belt power. Simplicity of construction, durability and ease of cleaning are some of its principal features. All parts being galvanized or tinned prevents rusting. Weight of the machine complete is about 38 pounds. List price, $25.00

Agents for DE LAVAL ALPHA SEPARATORS.

The Delaware County Dairy Association.

ED. HOARD'S DAIRYMAN:—A meeting of the Delaware County Dairy Association was held at Andes, New York, June 22nd. The representative farmers of Delaware County were in attendance, and discussed some important topics of interest to farmers. The president, Mr. R. Garrison, made the opening address in the morning. Some time was then given to the discussion of the financial condition of the society, and the appointment of committes. The president said that many members neglected to pay the annual fee, and the funds were not adequate for the needs of the society.

After some discussion of plans for collecting fees, the following was adopted: The secretary is to be provided with cards for holding coins. These, with envelopes for returning them, are sent to the delinquent members. These remind him about his fee, and furnish him a convenient way of remitting.

Mr. Elliott Graham, of Andes, New York, was the first speaker. His subject was, "To What Extent Can Sheep be Profitably Kept in Connection With the Dairy." He said that he had always kept sheep on his farm, and had made them profitable. Only a few sheep should be kept in the same pasture with cows. Too many will injure the pasture for the cows. On a pasture that will keep thirty cows, I think ten sheep could be kept without loss to the cows. If the fences are not good, you may have trouble with the sheep, and would not want to keep them on such a farm, unless you had good neighbors, for they will generally find the best feed in the neighborhood. You can, however, confine sheep with a fence made of six wires.

One good use of sheep is to kill weeds. If you have a field that is very weedy, build such a fence around it, and put so many sheep in it, and they will eat the feed down very close, and you may feed them a little grain if the pasture is not sufficient for them. Whether or not it will pay to keep many sheep, will depend on the condition of the farm and the help you have. If a part of the farm is rough, and not easily tilled, and there is not sufficient help to care for a large dairy, it may be profitable to keep more sheep, and less cows.

On a farm adapted to dairy farming, and with the help on the farm to care for the cows, I think the cows the most profitable. If many sheep are kept, they should be yarded, except when on the pasture, as they will injure the meadows, if given the range of the farm. I feed some ensilage to the sheep in the winter, for I think they need succulent food. I think the best time to have the lambs come, is just before grass.

Mr. John Dickson, of Andes, New York, was the next speaker on the subject of the "Profitable Use of Agricultural Machinery." He said, I do the most of my work by machinery, and I think it pays me. All farmers do not make machinery pay, because they do not keep it in order, and do not put their ground in suitable condition for using it. If a farmer uses machinery on rough and unsuitable land, it will cost him more to keep it in order than it is worth to him.

Questions—On a small farm would it be more profitable to buy machinery to do the work, than to hire the extra help needed to do it?

This depends on how cheap help can be hired, whether help can be got any time when wanted, and on the man who runs the machinery. A careful man will keep a machine, used on suitable land, in good order for many years, with only a small expense for repairs.

Would it be cheaper to hire some one owning machinery to do your work than to buy the machinery, keep it in repair, and provide a building in which to store it?

I do not think so, except on the very small farms. Unless a man owns machinery, he cannot depend on getting work done when it needs doing.

Can the average farmer in this county afford to use such expensive machinery as the hay loaders and grain binders?

The hay loaders do not work well, except on smooth, level land; with such land and a large haying to do, I think the loader would pay. The binders pay on large farms; on the small farm would hire a binder to do the work.

Mr. Wm. Hymers, of Delancy, N. Y., spoke of the change that had been made in farming by the invention of labor-saving farm implements. No one now would think it hardly possible to go back to the old way of doing farm work.

Mr. N. Jenkins, of Walton, N. Y., next read a paper on "Small Fruits and the Farm Garden." Mr. Jenkins has had considerable experience in farm gardening in connection with dairy farming.

To show how that with a near-by market for truck and with little help except the force required to run the dairy, it sometimes pays to cultivate a large garden by the use of the best labor-saving implements, using horse power to do most of the work, a large supply can be cheaply grown for market and home use, I will give quite a full extract of his paper:

"In the farm garden intelligent planning is needed for success. Study the best methods, and make the plan for the garden early in the spring. Order seeds in February, so as to have seeds ready for sowing the hot-bed, or in the house. It is poor economy to buy at the village store. Better ask several reliable seedsmen to send you their wholesale catalogue. Get some of your neighbors to combine their order with yours; order in quanties, and have the seeds come by freight. First in value in the farm garden, I think are peas. The area given to them should be liberal.

Be sure to plant several varieties. The extra early, the medium, and the late peas. Peas are easily grown. Plow furrows three and one-half feet apart, five inches deep, and drop the peas quite thickly. Cover about two inches deep, and when the peas are six inches high, draw more soil around them. The ground for peas should not be too heavily dressed with stable manure, or they will run too much to vine, and there will be less peas. Beans should be planted in plenty and variety.

In the winter when you are getting the year's supply of wood, is the time to provide brush for the peas, and poles for the running beans. Peas and beans are the best of food, rich in protein, and help to balance the ration for the farmer's family.

Sweet corn is another vegetable that can be had in large supply with but little labor. Varieties can be selected which will afford a continuous supply from mid-summer until late fall. Peas, beans and sweet corn I consider the staple crops in the farmer's garden. If one prefers, all these may be planted with the one horse corn planter and fertilizer drilled in at the same time.

The planting and cultivation being done by horse power, they are so cheaply grown, that the busy farmer can grow them in large quantities for home use, or for market. They are easily canned, and may be eaten the year round, and cheaply furnish the farmer's table with many good meals. The other garden vegetables require more work, and can be grown according to the time the farmer has at his disposal.

I wish to urge the farmer to do away with the little square garden plot, where everything is done with the hoe, and stretch it out to a good length. Plant everything in straight rows, and far enough apart for horse cultivation. Purchase a combined seed drill and wheel hoe, and you will be surprised at the amount of work you can do in a few hours, both in sowing seeds and cultivating the plants.

The farmer loses much who neglects the supply of small fruits. I am not the one who will tell you that they are as easily grown as corn and potatoes. It requires some work, and a knowledge of methods of culture to grow them well, but they are worth all they cost. I think it possible for farmers to have some product of the garden for the 1095 times during the year when the farmer's wife must solve the ever recuring problem, of what shall she get to eat.

Some time was given to the question box, and the following were asked and answered:

Is it good economy to build a round barn?

J. W. McArthur.—When you leave the square and approach the circle, you get more space for the material used.

I have a round barn. The bay for hay is in the middle, and the drive way is around the outside. The cows in the basement are arranged in a circle around the outside. The drive way on the second floor is used for storing wagons, and agricultural machinery.

Does it pay to feed grain when the cows have good pasture? Not when in full feed.

How can we get rid of the Orange hop weed? Grazing will not keep it down, the field must be cultivated until it is destroyed.

How can the hired man best gain the respect and confidence of his employer?

Mr. Grant.—One way is for him to be kind to all the animals, and especially to the farm team.

Why is buckwheat not a good feed for the dairy cow?

Mr. Grant.—I have fed buckwheat to cows, and when feeding it the butter will not gather I cannot tell why.

Mr. Hymers.—I have some experience in feeding green buckwheat straw when it did not fill well. It certainly increased the quantity of butter, and the quality was good.

Can butter be made cheaper in the butter factory than at home?

Mr. Mable.—If you have the help in your own family, make the butter at home. If you must hire it made, it is cheaper to have it made at the factory. Factory butter is more uniform in quality, and will sell for a higher price.

W. J.

Delaware Co. N. Y.

The Effect of Good Stabling.

[By J. S. WOODWARD, Lockport, N. Y.]

In a perfect stable with all the conditions just right, about 18 pounds of good mixed hay a day will be used by a 1,000-pound cow to simply exist. If no food is given beyond this, no production of milk can take place except at the expense of the cow's condition. Dr. Lehman made some very instructive experiments as recorded by Prof. Henry in his very excellent work, "Feeds and Feeding," in which a flood of light is thrown on this question of feeding cows. He shows that the same cow that was kept in the pink of condition on 18 pounds of dry matter in hay, ate all the way up to 25 pounds as she was placed in less favored conditions. That when turned out for a couple of hours each day, as cows are usually treated, she ate 21 pounds with no gain of milk production. He then continued to show the cost of milk production in food beyond this point. His experiments were so instructive that I compile and include the following table:

HOW KEPT.	Dry matter eaten.	Protein.	Carbo-hydrates.	Fat.	Nutritive ratio.	Milk Produced.	Lbs. of food for one lb. of milk.
	lbs.	lbs.	lbs.	lbs.		lbs.

In warm stable; out two hours each day	32	2.3	13	0.8	1:4.5	27.5	1.16

By this table we see that when eating 25 lbs. dry matter in the cold, no milk resulted, and the same when eating the 18 and 21 lbs. under more favorable conditions, so that in each case, the food eaten was entirely wasted so far as production of milk was concerned. That when eating the 25 pounds of dry matter, under ordinary conditions, 11 pounds of milk was made at an expense of 2.27 pounds of dry matter for each pound.

But as the ration was increased for each two pounds of dry matter, the increase of milk was about 5.6, and at a gradual reduction in the amount of dry matter, until when eating 32 pounds, it only took 1.16 of dry matter to produce a pound of milk.

The conclusions of the above turns a bright light on one grave mistake often made, that of deficient feeding.

A bright, clear headed man will look into this question, and will see that the milk costing the least is produced when the cow is fed an *abundant* ration, properly balanced. We have often heard farmers remark concerning a neighbor who was a liberal feeder: "Yes, I know he gets lots of milk, but it costs him all it is worth in feed."

By the above, it will be seen that it took just about half the food to produce a pound of milk when the cow was fed 32 pounds of dry matter that it did when she was fed 25 pounds, conditions being the same. Many feed their cows only about enough to maintain life. They get but little milk, and what they get costs high.

The Drouth and Its Probable Effects.

ED. HOARD'S DAIRYMAN:—Hardly more than once in a generation do we have so wide-spread and severe a drouth, so early in the season and long continued, as is being experienced this year. It is affecting nearly all of New England, New York and some of the other states in a greater or less degree.

It commenced early in the season, as we did not here get our usual spring rains, and have had but a comparatively small amount up to the present time, June 25th.

The effects are being very severely felt in some portions of the terriotory mentioned. From all around come reports of a short hay crop; in many places not more than half of the usual yield will be secured. This appears to be a foregone conclusion. Plentiful rains now would greatly benefit other crops, including pastures, but will be too late to help the mowing fields. They would, however, be of much use in starting up a second crop of grass and in replenishing the failing sources of water supply.

The dry spring enabled farmers to put their seed into the ground in the best manner, and with suitable cultivation the best has been done that could be under the circumstances to insure satisfactory crops at harvest time. This is our part of the work, and we must then trust in an over-ruling Providence for the rest, the sunshine and rains and conditions favorable for plant growth. But we have the promise of the "early and later rains," so then let us work in hope and wait.

In northern Vermont, crops, with perhaps the exception of hay, have done better than could have been expected, and if we are favored with seasonable rains for the next two months, the outcome must be fairly good, at least.

In one respect the farmers throughout this part of the country, where the drouth is prevailing, have reason to be grateful, and that is the large amount of old hay that is being carried over. This will help to supply the demands of trade and save many farmers from having to dispose of valuble stock at a sacrifice for want of forage to keep them. To me it seems poor policy for a farmer to feed out all of his hay from year to year, thus making trouble for him when there is a short crop. Far better to have a little left over for such a time.

Of course, farmers have been careful to secure their hay in the best possible condition, and have been doing all they can with the other crops to help make up for the deficiency, but thus far it has been too dry to expect much from late seedings of any kind. I hope ere this article finds its place in the DAIRYMAN there will have been a change for the better.

The pastures have been fairly good and cows thus far have done remarkably well, the yield of milk and butter being more than the average. This must be owing in part to better methods in caring for the dairy the past winter, the good effects of which are being felt even now. But the yield of milk is beginning to decrease, as should be expected this season of the year, and during July and August farmers will do well to take a little extra care of their cows, for these are usually trying months for them, and with present prices for milk and butter, and which from present indications, must continue, it will be found to pay.

The Franklin County Creamery Association made the hearts of its hundreds of patrons glad with the very liberal payment for May milk. A large sum of money was distributed among them at this time, and if this liberal policy—owing in part to improved methods in the business—can be maintained through the season, it will be one of the most convincing arguments in favor of the creamery management.

On account of the short hay crop, we can

hardly expect so brisk a demand and satisfactory prices for cattle as was the case a year ago, but as so large a number have already been disposed of, there may be no difficulty in getting rid of such surplus stock as may be on hand. E. R. TOWLE.

Franklin Co., Vt.

A New York Herd Record.

ED. HOARD'S DAIRYMAN:—I enclose a few figures from my herd of Holstein cattle. They were not forced, but had good liberal feed. Had no ensilage this year, or could have done better.

The four cows in brackets ate fifty pounds bran per day, which cost 40 cents, also twenty pounds clover hay each, cost $4.00 per ton, and what corn fodder they would eat clean.

I produced milk at less than 30 cents per 100 pounds; all high grade and full blood Holsteins. I recently drew 1,067 pounds milk in one day from twenty cows, and nine two-year-old heifers. No grain feed after turning to grass, and three cows being fresh in December. Average tests of entire dairy by state milk inspector in May, 3.4.

Jefferson Co., N. Y. GEO. T. MCNEIL.

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—The offering of butter on Monday's Elgin Board of trade was unusually light, aggregating but 8,520 pounds. All bids were at 18c and 1,560 sold at that figure, 1,860 pounds remained unsold, with 18c bid.

The only sale reported was Keystone 1,560 lbs. at 18c.

The sales for the corresponding week of the three preceding years were as follows:

July 2, '98, 26,100 lbs. of butter sold at 16c.
July 3, '97, 40,980 lbs. of butter sold at 14½c.
July 6, '96, 36,840 lbs. of butter sold at 15c.

Elgin, Ill., July 3, 1899. H. C. B.

DAIRY MARKETS.

ELGIN, Ill., July 3—Butter—142 tubs offered; 26 tubs sold; quiet at 18c.

CHICAGO, Ill., July 3—Butter—Creamery, extra 18c; firsts, creameries, 16½@17c; seconds 13½@14c; dairies, selections, 15@15½c; No. 1, 14c; No. 2, 12@13c; extra ladles, 12½@13c; packing stock, fresh, 12c.

Eggs—Fresh, at mark, cases returned, sold at 11@11½c; loss off, cases returned, 12½c.

Cheese—Full cream, Twins, new good to choice, 8½@8¾c; Young America, 8⅝@9c; Swiss, 11@13½c; Limburger, 7@8c; Bricks, 7½@8¼c.

Cattle—The market was active and prices were fully 10@15c higher. Exporters had to pay as high as 5.65. Distillery cattle, 1,170@1,377 lbs. sold at 5.35@5.45. Corn-fed Westerns, 5.25@5.65. The 1,518-lb. average cattle at 6 were the highest since March 20, when fancy Texas cattle sold here at 6. In February choice native cattle sold at 6.10. The bulk of the beef cattle sold at 5.25@5.50, or the highest of the year. Cows and mixed lots sold readily at strong to 10c advance. Stockers and feeders ruled dull, some 1,199@1,268-lb distillery bulls sold at 4.35@4.50.

MILWAUKEE, Wis., July 3—Butter—Creamery, fancy prints per lb, 18c; extras, 17½@18c; firsts, 16@17c; seconds, 14@15c; imitations, 14@15c. Dairy selection per lb 14@15c; lines, 12@13c. Market active; receipts 15,860 lbs and quickly taken by shippers, storage men and consumers.

Cheese—American Full Cream—New choice to fancy 8@9c. Brick—New per lb. choice, 8@8¼c. Limburger—New, choice per lb 7½@8c. Swiss—Drum, choice, 12½@13c; new block, choice, 10@10½c.

Eggs—Fresh per doz 12c, loss, off cases returned. Market firm and wants exceed the receipts, which are 321 cases.

AVOCA, Wis., July 3—Offerings on the Dairy board to-day were 1,539 boxes; market firm at 8@8⅛c for Twins, 8¼@8½c for Daisies, 7⅞c for Cheddars; all sold.

PLYMOUTH, Wis., July 3—Sales to-day 1,250 Twins at 8c; 75 Americas at 8¼c; 720 Americas at 8⅜c, and 240 at 8½c.

FOND DU LAC, Wis., July 3—Offerings 647 Twins and 750 Daisies.; market active at 8½c for Twins and 8¾c for Daisies.

MANITOWOC, Wis., June 28—Offers of cheese at Dairy Board to-day were 600 boxes Daisies, 100 boxes Twins, 800 boxes Young Americas. All Daisies and Twins sold at 8c, 338 boxes Young Americas at 8¼c and 462 at 8½c.

SHEBOYGAN FALLS, Wis., June 28—Sixteen factories offered 1,324 boxes of cheese on the call board to-day, and all were sold as follows: 293 cases Young Americas at 8⅝c; 509 at 8½c; 131 Twins at 8⅝c; 191 at 8½c; 30 at 8⅜c; 170 Daisies at 8¾c.

PLYMOUTH, Wis., June 27—Sales to-day 1,150 Twins 8¼c; 920 America 8¾c; market active.

CHILTON, Wis., June 28—The sales reported were 350 Twins at 8c, and 500 cases Young Americas at 8¼c,

BRILLION, Wis., June 23—Sales of cheese on the Brillion board 1,241 Daisies 949 Twins 8c, 365 Young Americas 8¼c.

SEYMOUR, Wis., June 27—On the dairy board there were 640 boxes Twins sold at 8c and 150 Daisies at 8¼c. Market active.

LITTLE FALLS, N. Y., June 26—This market is in just about the same position it was last week. Small cheese is firm at 7¾c, which is the uniform price for about all the sales. They are sold off on the average to June 10. The yield of milk keeps well up, feed being excellent and flies are not as yet giving any trouble. Buyers are filling some orders, but the bulk of the small stock bought doubtless goes into storage. The sales are: 89 lots, 6,449 boxes at 7¾@8c.

Butter—Sales of 37 packages dairy butter were made at 15@17c, the ruling price being 16c.

UTICA, N. Y., June 26—Notwithstanding the firm tone of the northern markets last week, nearly 4,000 boxes of large colored cheese were reported to have been sold at 7⅞c. A considerable proportion of large colored, however, sold at last week's ruling, 8c, and this was the ruling figure of the day, all grades being taken into consideration. The sales aggregated 141 lots, 10,093 boxes at 7⅞@8¼c.

The transactions on June 28, 1897, were 9,790 boxes, with 7⅜c the ruling price. The transactions on June 27, 1898, were 7,233 boxes with 7¼c as the ruling price.

There were no sales of butter officially reported. Outside the board, however, there were sales of 115 packages at a range of from 17@17½c, the bulk at the latter figure. There was a rumor that 18c was paid for a few very fancy lots.

OGDENSBURG, N. Y., June 26—On the street Saturday 1,335 boxes of cheese were sold at from 8½@8 9-16c; the bulk at the former figure.

CANTON, N. Y., June 26—On the board Saturday 2,332 boxes of cheese were offered. These were eventually sold at 8⅜c. There were 1,342 tubs of butter sold at 18c.

FULTON, N. Y., June 26—On the board to-day 19 factories were represented with 163 boxes of cheese. These were sold at 8c for large and 8¼c for small. No butter was offered.

BOONEVILLE, N. Y., June 23—The market to-day was firm. The sales were about 800 boxes of colored at 7⅞c, one lot at 8c and two large white at 8c. There were 250 boxes of small colored sold at 8⅛c.

WATERTOWN, N. Y., June 26—The total transaction were probably fully 7,000 boxes, of which 2,790 were sold at 8½c, 1,200 at 8⅜c, and the balance at from 8@8¼.

PHILADELPHIA, Pa., July 3—Butter—Receipts were not large, but offerings were ample for the demand, which was very moderate. We quote: Solid-packed creamery extra, 18½@19c; firsts 18c; prints, fancy, wholesale, 20c; average extra, 19c; jobbing, 2 @24c.

Eggs—Supplies were moderate and the market ruled firm, with a fair demand for fine, fresh stock. We quote: Pennsylvania, choice, fresh "loss off," 14½c; Western choice, fresh, in free cases, "loss off" 14½c; fair to good 13½@14c.

NEWARK, N. J., July, 3—Market quiet; 18½c for fancy creamery. Receipts liberal.

BOSTON, Mass., July, 3—No excitement on butter at 19c for best. Cheese steady at 8@8½c. Eggs—slow, 14@15c.

WASHINGTON, D. C., July 3—Market steady, extras 19c; firsts 18c.

NEW ORLEANS, La., July 3—Market easy; creamery 18½@19c. Stock accumulating.

Latest quotations for fancy creamery—Baltimore 19c, St. Louis, 18½@19c, Cincinnati 19@20c Buffalo 19c, St. Paul, 17½c, Minneapolis, 17c, Detroit 19c.

NEW YORK MARKET.

NEW YORK, July 1—Butter—Receipts for the week, 65,299 packages: exports for the week, 1,307 packages.

Refrigerators are filling up here, and there is more stock coming than can be consumed. The market is a little top heavy. Exporters are confining their purchases to low priced and low grade goods, and people, this week, have so scattered into the country that local consumption is light. Some speculative purchases aggregating, say, 3,000 packages of fine and extra creamery in long lines at 18@18½c may be noted. Fine ladle butter is quiet but holders are firm in anticipation of more export enquiry later on. N. Y. State dairy sells at 17@17½c for selections, and under grades sell at lower and irregular prices. We quote:

Creamery, extra 18½c; medium 17½@18c; poor 15@16c. Dairy, extra 17½c; medium 16@16½c; poor 14@15c. Ladle, extra 14½@15c; medium 13¾@14c; poor 12@13c.

Cheese—Receipts for the week, 44,048 boxes; exports for the week, 11,188 boxes.

The market is well cleared. Exporters and local trade bought freely and prices were advanced fully ½c per pound on the week's business. We quote:

Full Cream, extra 8⅝@8¾c; medium 8@8¼c; poor 6@7½c. Part Skimmed, extra 7¾@8c; medium 6@7c; poor 4@5c. Skimmed, poor 2@5c.

Eggs—Receipts for the week, 60,626 cases.

Arrivals were free this week and prices a trifle lower on all grades. We quote:

N. Y. State & Pennsylvania, per doz., 15½@16c; Northern & Western, best marks, 15@15½c; Western & Southern, 13@14½c.

DAVID W. LEWIS & Co.
177-9 Chambers St., New York.

BALTIMORE MARKET.

BALTIMORE, June 29—Butter—The receipts of separator creamery have been liberal, and the grading higher than for the previous week. As the sales have been limited almost to the daily distributive wants, much of this stock has gone into the freezers, some for account of the shippers, but the bulk of it is owned by the local receivers and they are by no means proud of their possessions, for notwithstanding the cheerfulness expressed by receivers elsewhere our merchants are ingenuous enough to admit that they would much prefer having no butter to carrying creamery, of no matter how high degree, at present cost. Gathered cream goods are in fair supply and the bulk of them have reached the limit of grading and have gone on the slide down to sour and summery, which is their annual fate. The bulk of the business now doing in this line, is in the varieties ranging from imitation creamery to store-packed, and this would indicate that speculators doubt the ability of the people to pay the price of the higher grades later on. Transactions within the low range of prices are as heavy as usual, and perhaps heavier; some large lines of packing stock have changed hands within the past two or three days. Blocks and prints are in moderate supply, and the demand shows an increase. Of store-packed, the receipts are light and the demand active for all grades.

"ALPHA" DISCS.

The system of milk dividing plates or discs used in separating bowls of the "Alpha-De Laval" machines makes all the difference in the world in the efficiency and general practicability of the cream separator.

A virtually complete separation without loss of a material amount of butter-fat in skim milk is possible only with the "disc" type of separator. This is particularly true with separation at low temperature or in running heavy cream.

The "disc" construction at same time permits of the separating bowl being made smaller and run at much less speed. 25,000 rev. will not accomplish as good results in the same bowl without discs as 6,000 rev. with them. Hence "Alph" disc machines require only about one-third the power of other separators, use only about half the fuel in power operation, and are three times as durable and easy to keep in repair.

The closer work of the "disc" system insures a smoother cream and a complete removal of dirt and fibrous matters, thus producing a higher quality of butter than is possible with any other separator or creaming system. The universal prize winning record of "Alpha" made butter bears witness to this fact.

"Alpha-De Laval" machines are as superior in mechanical construction as in scientific principle. The De Laval factories are reckoned among the finest machine shops in the world. The De Laval machines are not made for "cheap" sale and the item of cost does not enter into their construction, finish nor completeness. They are simply the best that can be made.

The De Laval catalogues illustrate all these matters in detail and can be had for the asking—"Creamery" or "Dairy."

The De Laval Separator Company,

WESTERN OFFICES: Randolph & Canal Sts., CHICAGO.
GENERAL OFFICES: 74 Cortlandt Street, NEW YORK.
BRANCH OFFICES: 1102 Arch Street, PHILADELPHIA.

Creamery Separator, extras 19c; firsts, 18c; seconds 17c. Creamery gathered cream, extras 18c; firsts 17c; seconds, 16c. Creamery Ohio, extra, 18c; firsts, 17c; seconds, 16c. Creamery imitation, extras, 16c; firsts, 15c; seconds, 14c. Iowa & N. W. Ladle, extras 14c; firsts 13c; seconds 12c. Ohio & Indiana ladle, extras 14c; firsts 13c; seconds 12c. Ohio store-packed, extras 12½@13c; firsts 12; seconds 11½c. W. Va. store-packed, extra 12½@13c; firsts 12c; seconds 11½c. Creamery Blocks (2 lb) extra 21c; firsts 20c; seconds 19c: Creamery prints (½ lb) extras 21c; firsts 20c: seconds 19c. Md., Va. & Penna. Prints extras 19c; firsts 18c; seconds 16@17c.

Eggs—Up to the first of this week our receipts were very light, hardly enough to supply the active demand. But for the past few days there has been quite a considerable increase in the receipts; the demand less active, and there is a greater disposition on the part of the receivers to effect sales. The buyers, on the other hand, are very choice in their selections, nothing but choice to fancy stock will satisfy them. All heated and other faulty stock is slighted. Market at 14½c.

Cheese—The receipts are ample for requirements; the market is firm as quoted; demand good.

N. Y. State—Cheddars, fine 9@9¼c; choice 8¾c; fair 8½c. Flats, fine 9¼@9½c; choice 9c; fair 8½@8¾c. Small, fine, 9½c; choice 9¼c; fair 9c. Ohio Flats, fine 9c; choice 8½c; fair 8@8¼c. Ohio Picnic, fine 9½@10c; choice 9@9½c; fair 9c Swiss cheese, fine 13½@14c; choice 12@13c; fair 11c.

J. M. LAMB & BRO.
301 Exchange Place,

FOREIGN MARKET.

BOSTON, July 1—Cabel advices of this date from the principal markets of Great Britain to Geo. A. Cochrane give butter markets as more active with prices the turn dearer. Danish selling at 21@22c; Irish 21@21½c, with finest Canadian in boxes bringing 19@19½c. There is a little better inquiry from speculators for ladles at 14½@15c, but there is very little offering. Weather conditions in some sections are not so favorable to the make, rain being badly wanted. No further advance in prices looked for at the moment.

Cheese markets are steady with values slightly higher in sympathy with higher quotations from Canada. Finest American and Canadian selling at 9¼@9½c.

READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

Wanted—To correspond with a first-class cheese maker. Address BOX 422, Cameron, Clinton Co., Mo.

For Sale Cheap—A fine Guernsey bull calf. GEO. W. McCREADY, Black Hawk, Wis.

For Sale—Creamery located in good dairy country. Three railroads and express companies. Market convenient. Address "CREAMERY," Lowellville, Ohio. 21-4

On July 21st, 1899, 1 p. m., the Mt. Pleasant Co-operative Creamery Co. will be offered for sale as a plant. If not sold as a whole, will be sold in parts on same date, Address MT. PLEASANT CO-OPERATIVE CREAMERY CO., Mt. Pleasant, Ohio.

Married man wants position on dairy or stock farm to take management or otherwise. Can run separator or make butter if necessary. Address H. J., care of HOARD'S DAIRYMAN.

Wanted—An honest and reliable man, capable of managing a large dairy. Must be experienced in all dairy work and with all dairy machinery. Liberal wages to good man. G. C. STREET, Houston, Texas. 18-4

Tamworths, ready to wean, $10 each, or $12.50 delivered. Hermanville Farm, P. E. I., Canada. 32-52

Exceptionally Low Rates to Denver, Col., via the North-Western Line. Excursion tickets will be sold at greatly reduced rates from all stations, June 25 to July 11, inclusive, limited to October 31, 1899, inclusive. Variable routes, delightful scenery. Apply to agents Chicago & North-Western R'y. 19-3

Exceptionally Low Rates to Denver and Salt Lake City, via the North-Western Line. Excursion tickets will be sold at greatly reduced rates from all stations, until July 11, inclusive, limited to October 31, 1899, inclusive. Variable routes, delightful scenery. Apply to agents Chicago & North-Western Railway. 20-2

Exceptionally Low Rates to Richmond, Va., via the North-Western Line. Excursion tickets will be sold at greatly reduced rates from all stations, July 10, 11 and 12 (but not for trains arriving Chicago before July 11 or later than July 13), limited to August 15, 1899, inclusive, on account of National Convention B. Y. P. U. Apply to agents Chicago & North-Western R'y. 20-2

Special Excursion Rates to Portland, Ore., and other North Pacific and Coast Points, via the North-Western Line. Excursion tickets will be sold at greatly reduced rates from all stations, until July 8, inclusive, limited to September 4, 1899, inclusive. Variable routes, delightful scenery. Apply to agents Chicago & North-Western Railway. 20-2

Excursion Tickets to Janesville, Wis., via the North-Western Line, will be sold from stations in Wisconsin, Michigan and Illinois at reduced rates, account of L. A. W. Meet, etc., to be held July 12-14. For dates of sale, limits of tickets, etc., apply to agents Chicago & North-Western Railway.

Excursion Tickets to Woodstock, Ill., via the North-Western Line, will be sold at reduced rates, from stations within 75 miles, July 12 to 15, inclusive, limited to July 17, inclusive, on account of Horse Races. Apply to agents Chicago & North-Western Railway.

Exceptionally Low Rates to Indianapolis, via the North-Western Line. Excursion tickets will be sold at greatly reduced rates from all stations. July 18, 19 and 20 (but not for trains arriving Chicago before July 19 or later than July 21), limited to August 20, 1899, inclusive, on account of National Convention Epworth League. Apply to agents Chicago & North-Western Railway. 21-2

Excursion Tickets to Madison, Wis., via the North-Western Line, will be sold at reduced rates, from stations in Wisconsin and certain stations in Illinois, July 17 to 31, inclusive. limited to August 1, inclusive, on account of Monona Lake Assembly. Apply to agents Chicago & North-Western Railway. 21-2

GOOD FOR GEORGIA.

Nothing finer in a literary way, has met our eye in many a day, than the welcoming speech Hon. Winter Wimberly, of Macon, Georgia, addressed to the Georgia Dairymens' Association, which convened in that city last December. We copy the following passages:

"The shepherds, tending their flocks upon the Chaldean hills, saw the glittering star that hung suspended like a jewel over Bethlehem; that star, that, in its mild refulgence, was the beacon light of humanity—it marked the spot where our blessed Saviour was born in a manger among the cattle. Little wonder is it that cows are held sacred."

* * * * *

"When the dairyman from every hill top shall lead his lowing herd to the music of their tinkling bells, in green pastures and by still waters,—then, O my countrymen, in that blessed time to come, the great God of nature will, upon the red old hills of Georgia, still bearing upon her naked heart, in her bare hill sides and rugged gullies, the serried scars of the whip of slavery, and the scourge of cotton, spread like a benediction of God a beautiful mantle of grass. All hail the coming time, and we, in anticipation, welcome you to our home and hearts."

A Ration With Separator Milk.

ED. HOARD'S DAIRYMAN:—H. B. C., Menomonie, Wis., writes: "If 100 pounds of water are added to 100 pounds of separator skim milk, how many pounds, and what kind of dry digestible matter must be added to the whole bulk, 200 pounds, to give it about the same feeding value as contained in the 100 pounds skim milk, prior to adding the water?"

Expressed in simpler form, our inquirer asks the quantity and kind of feeding stuffs which will furnish the same amount of nutriment as 100 pounds of separator skim milk.

Placing the nutrients of skim milk and the food substances chosen, we have the following:

DIGESTIBLE NUTRIENTS IN 100 POUNDS.

	Protein Lbs.	*Carbohydrates Lbs.*	*Ether Extract Lbs.*
Separator skim milk...	2.9	5.2	0.3
Wheat middlings.....	12.8	53.0	3.4
Linseed meal (old process).....	29.3	32.7	7.0
Mixture of last two....	21.1	42.9	5.2

A mixture of oil meal and middlings, equal parts by weight, contains the several nutrients in nearly the same proportions they exist in skim milk. A little calculation will show that between fourteen and fifteen pounds of this mixture will contain about the same nutrients as one hundred pounds of the skim milk.

These figures present a close approximation to the figures called for by our inquirer, but by no means cover the whole ground. In some recent experiments at the New York Station it has been shown that protein from animal sources is superior in feeding value for chicks and ducklings to protein from vegetable sources. These experiments open up a most interesting field for study and teach us most plainly that while feeding tables are useful and helpful, they do not always express the whole truth. While 15 pounds of the mixture named may, for some purposes, equal one-hundred pounds of separator skim milk in feeding value, it is doubtful if such is true with young animals.

There is much opportunity in this line for further studies at our experiment stations and all will await the results with interest. Meanwhile use skim milk wherever possible and extend it or supplement it by the use of materials similar to those here mentioned.

W. A. HENRY.

Wisconsin Agricultural Experiment Station.

A Dairyman on the Stave Silo.

ED. HOARD'S DAIRYMAN:—Last fall I built a stave silo 24×24, using the lumber rough, and edges not beveled, and I believe it has paid for itself in the one winter. Certainly, the better a silo is built the better it is for the owner, but I contend that a silo is *tighter*, and therefore *better*, by *not* beveling the edges of the staves, for the reason that the corners of the staves will mash together tighter than the flat edges, when beveled.

There is many a reader of your valuable paper who would, and I dare say will, build a silo of rough lumber, unbeveled, and by doing so probably change his business from a losing to a gaining one, while if he had to build one as expensive as is necessary to build a fine appearing one, he could not do it. "Big houses won't build big barns, but big barns will sometimes build big houses," and a silo can be constructed cheaply that will do the work just as well, and I believe last longer than an expensive one bought of a manufacturer.

Help the poor men to get on their feet. If the manufacturer can devise a way to build a silo cheaper, that will do the work as well as the unbeveled, home-made, he will benefit humanity, as well as his pocket-book.

I used a square silo, built the best way we could find out, from about 1888-1896, but with much loss. That silo cost about three times as much, per ton capacity, as my present one, and was not half so good. At that time, I conceived of building one just as I did build last fall, but had not heard of such a thing before. After a few years I found that they were being built that way and used with great success.

I expect to build two more, but would not bevel the edges if they were to pay me a bonus to do it.

Men of limited means: If you milk cows, you need a silo; do not hesitate to build a cheap one; get good quality 2×6's as long, or half as long, as you want the silo high; discard the unsound and crooked ones, and those with knots on the edges; you don't need to have them dressed or beveled; put up a scaffold, set up your 2×6's at places where hoops meet, put up two hoops, then your staves, one at a time, toenailing them together, and occasionally fasten it to the hoops; then put on the other hoops and draw tight, put on any kind of tight roof, (I have a round one with two dormer windows,) and fill it up.

I believe a good silo can be built for fifty to seventy-five cents per ton capacity, and the corn put in at an expense of one dollar to one dollar and a quarter per ton for the corn, and the cutting of it into the silo, making the cheapest and best cow feed we can get.

Des Moines, Ia. F. M. PARSONS.

Preservatives and the Human Body.

ED. HOARD'S DAIRYMAN:—Mankind is composed of numerous elements. They constitute the stuff that is necessary to fulfill the duties assigned to us during life. For every act we do, (mentally or physically) we have to draw on the above mentioned resources and they must, of necessity, be replaced by new material. This is called the process of waste and repair. If that goes on vigorously, it means health; if only sluggishly, it brings sickness; if it stops the result is death. Any substance, other than those elements, taken into the system is matter misplaced, and becomes a disturbing, disease promoting enemy.

It is thus easy to realize the vital importance of providing the above mentioned stuff (called constituents) in their purity. True that some of the organs have the power of eliminating noxious matter (non-constituents) from the system, but if they are taxed beyond their ability, become over worked, tired out, finally paralyzed and their usefulness destroyed. Then the blood, having lost its natural protector, gradually becomes surcharged with these foreign interlopers, and the consequence is, chronic disorders of innumerable forms, that only too often baffle the skill of the physician.

Antiseptics, called preservatives, that are not constituents (such as salt for instance,) must, from the very nature of things, antagonize the all important process of waste and repair, the aseptic is taking the place of the antiseptic. Among the great lights of medical science, experience has established the stubborn fact that since its use as a preventive, blood poisoning has increased to an alarming extent. Cleanliness is granted supremacy as a preventive at the present time.

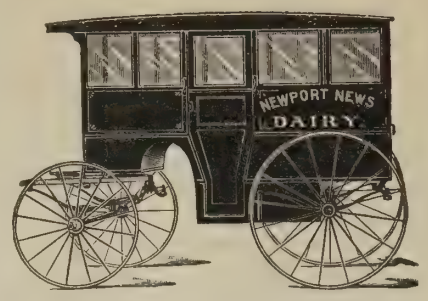
M. SCHEMBRI.

Rape Culture in the United States.

It is no exaggeration to say that for the past four years a thousand inquiries respecting the nature, culture and uses of rape have annually come to the office of the *American Sheep Breeder*. The impossibility of answering each of these inquiries in detail, through the columns of our paper, leads us to make the following general statement regarding this remarkable plant:

Generically, rape belongs to the same order as cabbage, kale, turnips, etc., and is a grazing and soiling plant, not susceptible of conversion into hay. It may be sown broadcast, or planted in drills from 26 to 30 inches apart, if desired for cultivation with the plow or cultivator. From four to five pounds of seed may be used for seeding broadcast, and from two to three pounds per acre if planted in drills.

For quickness and immensity of growth, it is without a rival; growing upon good rich soils to a height of 12 or 15 inches in six or eight weeks, and in its full growth three or four feet high, producing 20 to 30 tons of feed to the acre. Sheep, cattle or swine may be turned into the rape field when it has reached a height of 10, 12 or 15 inches, the owner always using caution to limit sheep or cattle to an hour, or less, of grazing for the first four or five days to prevent the possibility of bloating until they are accustomed to the feed.



For early summer grazing, rape should be sown about oat seeding time in April or May, according to the latitude, and for late summer and fall feeding, it may be sold in June, July and early in August. It may be sown alone for a fall early crop, or sown with oats, in which case it makes slow growth until the oats are harvested, when it comes forward with great rapidity. It is often sown on oat, wheat, or barley stubble, without plowing, and harrowed in with a light tooth harrow; in this way making an abundance of fall feed. As a supplemental crop, however, it is more extensively sown in corn, by scattering the seed ahead of the cultivator at the time of last cultivation. The corn shades and protects the young plant during its early growth, and within six or eight weeks lambs may be turned in for weaning. Rape in the cornfield is a paradise for lambs before corn harvest, and makes a splendid fall feed for sheep, cattle, or swine when the corn is harvested. In seeding the cornfield to rape it is a good plan to use about two pounds of rape seed mixed with half a pound of common flat turnip seed for each acre. The same mixture may be profitably used in seeding with oats or on stubble land.

The progress in rape culture in this country is one of the marvels of latter day husbandry. Five years ago the plant was little known and less understood. Last year millions of acres were devoted to its culture and other millions of acres will be added to its broad, green domain this present year. All progressive English and Canadian shepherds cultivate it mainly for sheep, but progressive American farmers are turning it to broader uses, having found it quite as profitable a grazing and soiling plant for their cattle and swine.

To say that rape is revolutionizing the sheep industry in this country is putting the case none too strong. It adds immensely to the popular tendency toward extensive sheep farming by yielding a vastly greater amount of succulent and healthful green food to the acre than any other crop, thereby increasing in like ratio the sheep carrying capacity of the farm. It tides the sheep farmer over the dry, hot season when the grasses are dead and the fields are brown, with a wealth of green, palatable and nourishing feed, such as no other product of the farm can or does furnish. It is alike valuable for the silo, for soiling the flock in the cool shadows of grove or barn in the scorching heat of the midsummer day, or for grazing the sheep in the cooler hours of morning and evening. Nothing equals it for ewes and lambs during the nursing period, and for weaning lambs it is incomparable, carrying them from mother-milk to self-sustaining lamb-hood with scarcely a sign of shrinkage. It is without a rival in all the list of succulent summer and autumn feeds for starting mutton sheep and lambs on the flesh-making road to full grain feeding.

It promotes the healthful growth of wool by furnishing the best wool producing food in the best elemental form. It furnishes more and better green food to the acre and at less expense than any other plant in all the long list of succulent summer feeds. It is not a feed of the week or month but carries the flock in perfect "bloom" from early June to bleak December. It enriches the soil with a wealth of nitrogen possessed by few other plants. There is nothing that can be succesfully substituted for it, because nothing in the whole range of plant life carries in such measure, the flesh-making, health-giving, life-inspiring, wealth-yielding elements that make the "golden hoof" and "golden fleece" the blest of heaven and the best friend of the farmer. To the rape culturist whether for sheep, cattle or swine, we give joy of his possession of this most generous product of his lands and toil! For sheep it is permanently the summer "feed for the million," and may its shadow never grow less on the American farm.—*Western Plowman.*

The World Cannot Show Its Equal

Hairy Vetch.

More attention is being given to this plant, which is new to Michigan, and there are some farmers experimenting with it at this time, and it will be a good idea for many more to sow a small plot and learn, in a practical way, something of its habits. Concerning it, the Michigan Experiment Station has published this:

"This plant has also been called Villous vetch, Sand vetch, Winter vetch, Russian and Siberian vetch. It is a native of Western Asia and has been cultivated to some extent in Europe for about fifty years, particularly in northern Germany. Other species of vetch are cultivated in certain parts of Europe more largely than this one, but within the past few years hairy vetch has received increased attention both in Europe and America. This plant is of special interest to growers in this country on account of its hardiness, and its prospect of filling a place not fully occupied by any of our other leguminous crops. Then, too, while some of the other vetches have been of greater value in Europe, this one appears to be the only species which, thus far, has shown a fair prospect of success in the United States. Among the inquiries that have come to the station regarding this plant, within the past two years, several are from seedsmen who have been investigating its merits with the view of offering the seed to their customers.

"This vetch is usually considered a winter crop, but it may be sown in either fall or spring. In this locality, self-sown seeds usually germinate in the fall, and the young plants live over and produce a crop the following season. A plot sown to hairy vetch will thus maintain itself year after year. It is recommended abroad to sow the seed with oats, as is done in this country with field peas, and harvest both crops together, for feed. In the spring of 1896, this station sowed half an acre of mixed oats and vetch according to this plan. The vetches, however, made practically no growth until after the oats were harvested, although the young plants maintained their existence. After the oats were removed, there was a plentiful supply of rain, and the vetches came on and made a vigorous growth. Our notes on August 19 says: 'Villous vetch sown in oats last spring is now thrifty and as high as the oat stubble—a few flowers are seen.' Three days later the statement appears: 'Vetches growing rapidly and now hide nearly all the stubble.' Growth continued luxuriant through September, but was checked by the frosts of October, although the foliage was still uninjured.

"On November 12, five square rods were cut and weighed, furnishing 430 pounds of green forage, or at the rate of nearly seven tons per acre

Our experience in feeding this vetch was somewhat unsuccessful at first. During about six weeks, the rams belonging to the college were pastured on rape and crimson clover in an enclosure adjoining the plot of vetch, and from time to time small quantities of the latter were cut and given to them. This was eaten quite reluctantly, although the pasture was very short. A little later, two valuable rams, newly purhcased, were fed in the stables on green rape and vetch. At first the rape was eaten freely and the vetch with some hesitation, and after a few days the rams refused the vetch altogether. Later in the season, as cold weather came on and other green feed became scarce, some of these vetches were cut and fed to cows and

sheep. The cows ate them heartily; the sheep not quite as well. Possibly the frosts of autumn may have modified the flavor of the vetches, somewhat, or the result may have been due to the keener appetites of the stock as colder weather came on. Vetches are highly nutritious, even more so apparently than clover. An analysis quoted in a circular on this plant, issued last year by the Department of Agriculture gives their content of protein, or nitrogenous matter in the dried material, as 22.78 per cent. It is not at all uncommon for stock to refuse leguminous plants as food, or choose the ordinary grasses in preference, notwithstanding the higher nutritive value of the legumes. With a little care in feeding, however, it is well-known that the pea vines, bean straw and other fodders of this class are eaten by most kinds of stock, and prove highly desirable foods. We think, therefore, that no one need have any apprehension that this vetch cannot be made available as fodder, or that any reluctance that may have been manifested by stock toward accepting it cannot be overcome."—*Practical Farmer.*

Close Hits.

That practical Iowa dairyman E. C. Bennett, in his "Dairy Department" of the *Northern Post* fires in some bulls eye hits. Here are a couple of them.

Terry tells of two cows bought at the same time by his boy. One of them was of the dairy type, and one the dual-purpose type. The latter gave fifty pounds of milk when fresh, but dried fast. The two were kept two years, and the dual-purpose cow was then sold for beef at $38, while the dairy cow would, perhaps, sell for half that, for the same purpose. But in the two years, the one with the dairy form gave $38 more of milk, and he has her yet. The two cows have, therefore, yielded exactly the same amount of money, but one is still alive and earning money, and the other is dead and in the city sewers, and will never again be heard from. Which is the better cow?

We lately ran across a contented farmer. He sold 231 pounds of butter from twelve fresh four-year-old cows for thirty days. He keeps dual-purpose cows, feeds hay and ground corn and corn meal, and sets the milk for the cream to rise, sells the butter at the store at 15 cents. He is satisfied, because he has not learned how he is missing his opportunities. He ought to have fifty per cent more butter. Better feed and a separator would have gone far to accomplish this with dual-purpose cows, either at home or by patronizing the creamery, and good dairy cows would have gone beyond these figures even. Hay and corn alone is not a fit feed for a cow in milk. It lacks nitrogen. If the hay is clover it helps matters, but a hay and corn diet means a limited yield every time.

A Growing Industry.

The Marengo Sugar of Milk Factory Is Increasing Rapidly.

One of the industries of Marengo is the Marengo Creamery and Sugar of Milk Company. This company was organized about a year ago. There are eight men employed in the factory here, and three at each of the eleven factories, whose product is made up here, making all together forty-one men who are in its employ. The Marengo Creamery and Sugar of Milk Company make butter, curd or cheese, and sugar of milk. They handle the product of eleven creameries, which are scattered around Marengo within a radius of twelve miles. The milk received at the factories is first passed through separators, extracting the cream, which is made into butter. The skimmed milk is then heated to a certain temperature and curdled with acids; the curd is then taken to the refinery at Marengo, where it is first ground in sausage mills, then dried by a hot air blast. When it is thoroughly dry it is ground to the fineness of corn meal. It is then ready for the consumer, and is shipped in sacks to paper manufacturers who use it for calendering or polishing of paper. It is expected that the output of curd for the coming spring will reach 100,000 pounds per month.

The whey of milk that remains after the first process is crystallized into sugar in a solution from which it emerges absolutely pure and white.

For domestic trade it is nearly all put up in barrels, and for exportation is neatly cased in boxes.

The company, though in its infancy, is now exporting sugar of milk both to Germany and Japan.

The sugar of milk is nearly all used for medical purposes, for the coating of pills, discs, pellets, and in the combinations of lactated foods and patent medicines.

The product of sugar of milk for the year amounts to about 400,000 pounds. Aside from the manufacture of sugar of milk, the company maufactures and sells from 750,000 to 1,000,000 pounds of the finest creamery butter.—*Ex.*

Milk Fever.

Characteristics of the Disease.—Treatment and Prevention.

The New Jersey Experiment Station has issued an excellent bulletin on milk fever. It is claimed that one form of the disease is caused by germs. This may count for the fact that, in some herds and barns, milk fever seems to be contagious.

Treatment should begin a week or two before the calf is expected, and should be practiced on every cow whose condition is such as to lead the owner to fear the occurrence of milk fever when she calves. The treatment is to continue for a week after calving. Begin giving short rations; feed sparingly of rich food, such as grains and clover; rather give apples and bran mash. Give salt to provoke thirst, and encourage the cow to drink, by warming the water, if it is cold. Large doses of Epsom salts, (a pound to a quart of water,) may be given once, or even twice, a week, to provoke an unwonted activity of the bowels, and to counteract the tendency of constipation. If the udder is distended, it should be rubbed and milked regularly. The cow should be kept in a place which is dry, clean, airy and cool in summer and warm in winter, away from the other animals. Should the owner fear that his method has not succeeded in reducing the blood sufficiently, as may happen when the time is short, a veterinarian should be called to let out several quarts of blood from the jugular vein of the neck.

Just before calving the vagina should be washed out with a generous injection of two per cent creolin solution, which should be repeated daily, after calving, for a few days. Immediately after the calving is completed the veterinarian should inject creolin solution into the uterus, as in cases of abortion. Neither carbolic acid nor corrosive sublimate nor iodoform can be recommended for disinfecting the genital passages, but these disinfectants and others may be used liberally upon the soiled bedding, barn floor, etc. If the cow is down, she should be propped up on the brisket, to prevent the running of food into the lungs, from the stomach.—*Ex.*

Buhl Sunlight Milk Cans.

NOTICE OUR PATENT BREAST and BOTTOM HOOPS.

These cans are properly shaped, well tinned and easy to clean. They will last twice as long as any other low priced cans on the market. If your dealer has not got them, send your order direct to the makers and instant shipment will be made. Capacity 5, 8 and 10 gallons. Write for Handbook No. 32, "A Study in Milk Cans."

BUHL STAMPING CO.,
Mention HOARD'S DAIRYMAN. **Detroit, Mich.**

Gluten Feed is used by nearly all successful dairymen, and has become a necessary article for any dairyman farmer who wishes to keep pace with the successful men in his line of business.

Gluten Feed increases the flow of milk, improves the quality, keeps the cattle in the best possible condition—in fact, helps you make more money out of your dairy. This is not cheap talk. We mean business. Gluten Feed is all and more than we claim for it, and, best of all, a trial proves it. Sample of Gluten Feed, Milk Talk Pamphlet, and circular illustrating the "Value of Butter Fat in Milk," all FREE if you address

And CEDAR RAPIDS, IOWA.

Selecting a Cow.

Having decided what kind of a cow is wanted on the place, or what the cow is wanted for, the next thing is to select the individual cow for the purpose. The shape and style of the cow being the first thing to take the eye, fix in the mind the type of a good cow for milk.

Without going into the detail of points, as given by some writers, which might be varied also for different breeds, remember that the good milker is wedge shaped when looked at directly in front, that is, with slim, flat neck, rather thin through the shoulders, thick and deep in the body, to give abundant room for her digestive organs and the food they contain, and broad across the hips.

The head should be carried well up, or not drooping when not feeding, broad between the eyes and rather long and narrow below them down to the nose, with the eyes large, full and clear looking, but not staring, as if scared. The wild-looking eye denotes a wild cow, not always pleasant to handle, possibly cross, while the dull, watery eye is a sign of lack of vigor, if not of actual sickness at the time.

The forelegs large above the knee and small below; the thighs, thin and flat and well spread apart behind by the udder, the hoofs not too large and of a clean, waxy look, and well set on the ankles. Beware of a long ankle, particularly if not erect, lest it result in bone ail, or "cripple ail," which disease has been variously attributed to inbreeding and to a lack of bone-forming material in the food, and, as I think, is the result of the latter cause, seldom occurring on a limestone soil or among herds where wheat bran is liberally used for food.

The udder should be the main point of observation. This should be large, and run well forward, as well as broad behind, with the teats well spread apart, and the latter should be of convenient size to grasp well in the hand. In the Jersey grade it is more apt to be too small than too large. The udder should be soft and skinny rather than fleshy when empty. Too much or too long hair on the udder is considered a defect, though some very good cows have more hair there than some poor ones. It is an indication of coarseness rather than of poor milking capacity, and such cows do not usually respond quickly to a change in feed, whether for the better or worse.

A fine, soft and silky coat of hair on the body is usually an indication of what is called an easy feeder, that is, one which will quickly show by an increase in amount of milk or the thickness of the cream, or by taking on fat, when she is being well fed. Of course the harsh, wiry hair indicates the reverse under the same conditions, but it may be only proof that the animal has not been well fed or well cared for. Cold barns and exposure to cold storms may cause coarse, wiry hair, long and standing out, unlike the smooth, slick coat of the well-fed animal in a warm stable, and it may be a symptom of an unthrifty condition, if not actual sickness.

Such a cow may improve greatly under an improvement of her care, but the novice would do well to pass them by, and let those more skilled in the care of cattle, handle them.

If the cow submits quietly to being handled, she is of a quiet disposition, and the udder should now be handled and the teats tried. If she is a bad kicker she will be apt to let you know it, and it is better that she should kick you once before you buy her than twice a day afterward. See that she milks easily. Some cows milk so hard or give so fine a stream that it is worth nearly the value of the milk to get it from them.

Look at pasture fences and see if they have been made extra high and strong to keep in the herd, or if they have been frequently broken down and mended. Even though she may not be the rogue that has done such mischief, one breaking cow in a herd soon teaches others to follow her example, and when they have once learned the trick of breaking bounds it is not easy for them to forget it.

It is seldom well to buy a cow of one who has pastures much better than yours, or who feeds more liberally of grain than you intend to. The old Quaker who sold the cow that did not give as much milk as he claimed said to the buyer, "Thee should have bought my pasture too." A cow that has long been kept by a milkman is apt to have been grain fed up to her full capacity, and will not do well on less liberal rations.

A cow from a large herd will often run more quietly alone than one which has been kept with only one companion. I never like to buy any animal of an ill-tempered man. He is apt to soon make them as ill-tempered and fractious as he is.

The cow is in her prime when from six to nine years old if she has been well cared for, and if I were to buy a cow for family use I should prefer to buy her when fresh after her first calf, that by care I could establish the habit of keeping up her supply of milk until she was nearly ready to drop another. Then for three or four years she would be growing more valuable each season.

One not used to the care of cows, may do better to buy an old cow that is fresh in milk, and after the calf is two or three weeks old, begin to feed grain, gradually increasing the amount given, so that in six or eight months the cow would be nearly ready to dry off and fat enough to sell to the butcher. It is true that old cow beef sells at a low price, and there might not be much profit in the transaction, but there need not be any loss. The milk should pay well for the feed, and the owner would be gaining in experience without fear of much loss, which might not be the case when he experimented with a valuable young cow.

If one desires to keep more than one cow for butter making they should be as much alike as possible in two respects at least, the time which is required for the cream to rise on the milk, and that taken for churning the cream. If they differ there will be apt to be cream thrown out in the skim milk or buttermilk, and perhaps in both.

I have never known a large record for butter made by a herd of cows unless they were all of one family, but when one cannot raise his own stock he should buy them as much alike as possible. Then the same feed and care will produce similar results in all, and the cream, all requiring the same amount of churning, will all be alike churned.

Of course this may not be the case when one cow is fresh in milk and another far gone with calf, but even then their cream churns together better than if they are of breeds not alike.

These hints are intended for the new beginner rather than for the experienced farmer or farm hand, but there are some who have fed cows and milked them for years who really know but little more about selecting a good cow or herd of cows than the daily passenger on the railroad would know about selecting a locomotive. They have learned to do their part of the work each day, as they were directed, but know but little of the reason for doing the one way or some other way. They had imitated, but not learned.—AMES in *American Cultivator*.

Calf Raising.

From the earliest history of the human race, whether recorded or a matter of mere tradition, the cow and her calf have been the almost indispensable companions of man. They have furnished him milk, butter, cheese, veal and beef, and in addition materials for boots, shoes and robes. They have furnished glue to the cabinet maker, hair to the upholster, buttons to the tailor, and delicacies innumerable to the sick. Without the cow and her calf, this would be a sad and dreary world.

During all these years and ages calves in countless millions have been grown and the problem has been so simple and easy that it has been left to the hired girl in the countries of the Old World and to the hired man, or to the oldest boy or girl, in the New.

The problem of raising the calf was easy then, nor is it any more difficult now, over large sections of the world where cattle are grown under practically patriarchal conditions; as, for example, in the vast range country comprising two-fifths of the United States; in all sections, North or South, where it will pay, on account of the cheapness of the land, to keep a cow a year for the chance of a calf, on the vast ranges of South America, Australia, South Africa, the plateaus of Central Asia, and on some portions of our tropical islands. Nature's method of growing the calf, when the comfort of the cow and the calf and not the interests of the owner are to be considered, has not been improved and never will be.

In the development of civilization, the time comes when the human family appreciates the value of milk, butter and cheese. The mechanical instincts are developed, the intincts also for trade and traffic, the system of the division of labor is adopted, each man doing what he can do best, and each farm, section and country producing what it can produce to the best advantage, cities grow, and there is a market for dairy products, for beef, and all the by-products of the animal. Necessity then compels the farmer to milk cows. It requires some sort of compulsion. We do not believe that any man naturally likes to milk. He, however, adapts himself with more or less grumbling to the new conditions. He sells the calf for veal and when the demand for milk and butter creates a price in excess of the value of the veal, he deacons the calf, that is, kills it on sight, and thus avoids the other equally disagreeable task of raising the calf by hand.

As agriculture develops still further, the farmer finds the need of the matured calf, both to keep up his stock of cows, and to supply himself with the means to use, to the best advantage, the coarse grain, the fodder and the summer grass of the farm, converting them into marketable products; or, to change the figure, he needs to grow packages in which to condense these products, and save freight, and he then reluctantly undertakes to teach the infant boss to look down, instead of upward for its nourishment, and to drink instead of suck.

Usually, on the farm where but few cows are kept, and where the butter is made at home, there is some member of the family who has the patience, even temper and tact required for this bovine education. The methods of separating the cream from the milk that have been in vogue in all lands from time immemorial down to the last ten or fifteen years, have uniformly failed to secure the complete recovery of the butter fat, and, hence, have not thrown the ration so badly out of balance, as we might at first suppose. The modern dairy cow gives richer milk than the cow of the patriarchal ages of the range. The old-fashioned skim milk, fed sweet, contained from one-fourth to one-third of the butter fat during the summer season, in which three-fourths or more of the calves are fed milk, and, hence, contained

Fancy's Harry-Tormentor Bull Calf 10 mos. old.

Hood Farm Jerseys Choice young bulls, partaking of the blood of the great World's Fair Winners, Brown Bessie and Merry Maiden, generally on hand for sale. Remember the bull is one-half the herd. All young stock will have 50 per cent of his blood. You should therefore have the best you can get. Write to HOOD FARM, Lowell, Mass., and you will be likely to find just what you want and at a reasonable price.

Introduce Milking Jersey Stock INTO YOUR HERD
by buying one of our bull calves, Our herd of 325 has been bred for milk for 17 years. Best blood, size and constitution. Selected stock. **Large English Berkshires,** all ages, at their best. Write for our "little book."
FILSTON FARM, Glencoe, Md.

High-Class JERSEYS
The blood of Combination. (Sire of **25** in list) through Brown Bessie, (Champion Butter Cow at World's Fair), and Diploma 16219 sire of 48 in list including Merry Maiden. Young bulls, also cows and heifers bred to Recorder 29239—son of Brown Bessie. Printed pedigrees. State what is wanted.
H. C. TAYLOR, Orfordville, Wis.

We Have Sold
SEVERAL OF **The A. J. C. C. COWS** advertised March 17th (see page 92), in fact we quoted prices that made them desirable. There still remain some as well bred as those sold, which we think **genuine bargains.** We also have a few heifers that will be right to breed at time of turning out to grass. For cows, write for List No. 3, giving short pedigrees; for heifers, List No. 2.
WINTERGREEN HILL FARM CO., Scottsville, N. Y.

Pure Bred **Tamworth Pigs,** Bacon curers choice. Pure Bred **Ayrshire Cattle,** largest imported herd in America. Stock all ages for sale, R. G. STEACY. Box 720 Brockville Ont., Canada.

A Good ST. HELIER Bull Calf
- - Sired by Osprey, 17385. - -
72 per cent St. Helier, out of a daughter of Stoke Pogis of Prospect. Well grown, strong and vigorous. One year old. Ready for service. For sale at reasonable price. For pedigree and price address. C. A. SWEET, Buffalo, N. Y.

St. Lambert **Jerseys,** all ages, both sexes. Some from **tested cows** at low prices. W. J. HUSSEY, Mt. Pleasant, Ohio.

THE Evergreen Farm Herd of A. J. C. C. Jerseys is now headed by St. Lambert of Brodhead, whose pedigree is unequaled in the northwest. We should be pleased to have any one in want of Jerseys to write us for catalogue, stating just what is wanted. N. N. PALMER & SON, Brodhead, Wis.

ST. OMER HERD
Choice lot of Exile and Signal bulls now ready for service. All stock tuberculin tested.
JOS. T. HOOPES, Bynum, Md.

GREEN PLAIN HERD
POLLED JERSEY CATTLE
Recorded stock FOR SALE. Inquiries promptly answered. W. H. FORBES, Clifton, Ohio.

Diplomas Combination 39962.
For Sale—Bulls and Heifers by him out of Fancy's Harry. Signal cows, some of them tested. Write us. J. E. TYRRELL, Marysville, O.

ONE YEARLING BULL
Out of a tested dam and **TWO BULL CALVES** out of large milking dams, for sale. Write for price. W. R. THOMAS, Bellmore, Ind.

PROSPECT HILL JERSEY HERD.
WISCONSIN PRIZE HERD.
Young Stock from **400 Pound Cows** for sale. Come and see them. **TUBERCULIN TESTED.**
F. H. SCRIBNER, Rosendale, Wis.

Linden Lawn Farming Co., OLNEY, ILL.
Estab. '90. (*Capital Stock $100,000.00.*) Inc. '97. **640 ACRES.** Breeders of Jersey and Aberdeen Angus Cattle. Poland-China and Yorkshire Hogs, Pure bred Poultry. Send for our plan of Co-operative Farming and Investments. C. S. MACE, Manager.

J. D. THOMPSON, Superintendent.
FRED P. STORY, Herdsman.

JOLIET, ILL.,
H. N. HIGINBOTHAM, Prop.,
. . BREEDERS OF . .
Fancy Jersey Cattle.
Service Bull,
PEDRO'S HANDSOME PRINCE, NO. 42794.
The cows in this herd are of the best families of milk and butter producers. We have for sale young bulls by Pedro's Handsome prince and Exile of St. Lambert 55, No. 36073, out of tested cows. Write for prices and pedigrees.

For Sale . . . BULL CALF,
Grand-son of the great **Exile of St. Lambert 13657,** sire of 72 tested daughters, "more than any other bull, living or dead." He is thrifty and good size; solid fawn color. His dam has a butter test of 15 lbs. 8½ oz. in seven days. He will be sold cheap.
P. J. COGSWELL, Rochester, N. Y.

Biltmore Farms' JERSEYS.
This is a working herd of 250 of the best native and imported breeding, selected for work at the pail, constitution and individuality. All Tuberculin Tested. Above the fever line, so we can ship anywhere.
SOME CHOICELY BRED
Bull Calves
out of great cows and by the best sires, for sale at Dairymen's Prices. Also large **English Berkshires,** imported and native bred. Apply to
GEO. F. WESTON, Supt., Biltmore, N. C.

MILLER & SIBLEYS JERSEYS.
Ida's Rioter of St. L. leads all other bulls in average for 29 tested daughters, viz.: over 20 lbs. of butter apiece in a week. All full weekly tests, by eight different owners. He weighed 1,760 lbs. His dam's record, 455½ lbs. milk, 30 lbs. 2½ oz. butter (official test) in 7 days. **FOR SALE**—Grandsons and granddaughters of Ida's Rioter of St. L.; also cows in calf to his sons.
224 First Prizes and Sweepstakes at 22 State Fairs or great Expositions. Big cows, Sound cows, Heavy Milkers and Great Butter Makers. Our Adelaide of St. Lambert gave 82¾ lbs. milk in one day, 205¼ lbs. in one month, the world's Jersey record. Many other championship records. No catalogue. Special literature sent if this paper is mentioned. No animal sold for less than $100. Lowest price for quality. Every animal tuberculin tested before sale, if desired. Also for sale, Children's Ponies and Imported Shropshire Sheep.

Franklin, Venango Co., Pa.

The Lone Tree Jerseys
THE largest collection of **high testing cattle** in the West, including **home-bred** and **Island cows. Show** and **Breeding Stock** always in supply. **Especial attention** given to furnishing **foundation stock for pedigreed herds.** A superb lot of young bulls and heifers now in special offer, including some sure prize winners.
Introduce Fresh Island Blood Into Your Herd.
SIRES IN SERVICE:—The prize winning **IDA'S RIOTER OF ST. LAMBERT 10th,** the champion **CATONO KHEDIVE,** the champion **CZAR COOMASSIE,** and **IMP. GOLDEN BAR,** inbred through his sire, Aristocrat, and his dam, Imp. Sandgate, to Golden Lad, the greatest bull on the Island of Jersey.
Write for what you want. Visitors always welcome. JOHN E. ROBBINS, Greensburg, Ind.

from one-third to one-half as much butter fat, as the milk of the cow under range, or natural conditions. With care, and a little supplementary feed of corn meal, or its equivalent, a fairly good calf could be grown, which, at the end of the year, could not be readily distinguished, when in the best hands, from those fed in nature's way.

The development of the railroad system, with its refrigerator service, rendered the creamery possible and led to the transfer of butter making to it, from the farm. The introduction of the separator at the creamery, with its perfect and complete separation of butter fat from the milk, and the necessary location of this creamery at or near the station, miles from the home of the calf, has radically changed all the conditions under which the calf is reared.

First, by removing the butter fat completely, it changes the ration so radically, that under no circumstances can the calf be properly nourished by separator skim milk alone.

Second, the delivery of the milk at the creamery, and the return of the skim milk, requires a lapse of from twelve to twenty-four hours from the time that the milk leaves the cow's udder, until it reaches the stomach of the calf. During this period, the germs, which cause acidity, get in their work, and the result is, that often the milk becomes sour, thus impairing digestion, and developing the disorders common to the young of all animals, especially during the summer season. In short, the cow in the state of nature, feeds her calf on a perfectly balanced ration. She feeds that ration sweet, warm and often. Under the conditions created by the gathered milk separator system, the calf is ordinarly fed a totally unbalanced ration, sour, cold and seldom—twice a day at the most.

Is it then any wonder that the patron who has given no attention to the chemistry of milk and the changes which it undergoes under our climatic condition, who has never studied the balanced ration, and to whom the milk is delivered sour, or sweet one day and sour the next, concludes that separator skim milk is worthless, if not positively injurious to the calf. Even before the separator system came in, it had become a maxim in the West that "When the creamery comes in, good calves go out," and for two reasons: The introduction of the special dairy cow, whose calves lacked beef qualities, and also because farmers had so long been used to growing calves in nature's way that the art of growing had been lost to the greatest portion of the generation that has grown up since the first settlement of the prairies of the West.

Meanwhile, there is a great and ever pressing demand for calves of beef quality to consume the products of the empire of virgin soil opened up in the last forty years, and to fit these products for shipment to the world's markets, and as a result prices for calves are higher on a gold basis in themselves and have a higher exchangeable value than has ever been known in the history of the nation. There has been a steady decrease, partly from the causes above mentioned, and partly as a result of the emptying of the range because of short feed and hard times during the past seven years; a decrease in the absolute numbers of cattle, and a still greater decrease in the number in proportion to population. The great ranges now carry about as many cattle as they can, with safety. The demand for veal, milk, butter and cheese in the cities, limits the capacity of the Eastern states and foreign countries to furnish young cattle, until it has become an economic necessity, now generally realized, state wide and nation wide, for the prairie regions of the West to increase the number of well fed and well nourished calves.

To point out how this increase can be made with profit to the farmer and the creamery alike, and to obviate the difficulties created by the separator system, is the object for which these articles are written.—*Wallaces' Farmer.*

A Scotch System of Ventilating a Cow Stable.

At a recent meeting of the Glasglow and West of Scotland Agricultural Society, Mr. Alex. Blair gave the following method of ventilating a cow stable:

"In the outside wall, opposite every pair or cows, and just on the level of the floor, is placed a large grating, admitting a full half square foot of air, exclusive of the ribs of the grating; the air passes through this, over the hot pipes, and up through the inlet into the byre, which, as I stated before, is placed on the top of the heating chamber, and in front of each pair of cows. The gratings on these inlets are made on the hit-and-miss system, so that the flow of air may be regulated in the stormy weather. The flow of air provided for each cow, when the wind has a velocity of three miles per hour—and it is seldom we have it of less velocity than this—is 3,600 cubic feet per hour, a quantity which should be sufficient to satisfy the most rabid advocate of fresh-air ventilation. The roof ventilation is carried out on an entirely new principle, and it may be worth while to describe it to you rather minutely. The system of this ventilation is such that it is impossible to close it, and yet there can be no down draught, which is such a bugbear in the farmers life with regard to weeds in milk cows. In outside appearance the ventilator is an ordinary louvre ventilator, running the whole length of the ridge of the byre, except a few feet at both ends. The sides of the ventilator are solid boards for a height of 12 inches, and the louvre boards are above this, the whole being covered with a corrugated-iron circled roof. A division runs along the inside the whole length of the ventilator, and every 4 feet is divisioned off crossways. In this longitudinal division holes are cut about 12 inches square, and in front of them the sarking of the main roof is cut away. In these square holes frames are placed on which are hung silk valves. All air passing to the outside must pass through these valves, and nothing whatever can enter. In addition to these valves there is provided a hinged flap behind each pair, which is controlled by a rope, and can be opened in calm weather. This means that, practically, the whole ridge is opened up at will, for roof ventilation. This ventilator has been put up on several byres, which had only the common louvre ventilator, with excellent results; in one case the milk supply was very materially increased, to the benefit of the farmer, although I am of the opinion that the landlord ought to have shared it with him. The heating apparatus consists of a slow-combustion Canadian boiler, situated at one end of the byre, in a pit, from which the four rows of pipes, going along each side of the byre, are fed. The pipes are four inches in diameter, giving fully a square foot of heating surface for every foot of pipe, and as there are 560 feet of piping there is fully that number of square feet of heating surface available. The cost works out about 40s per cow. The open winter, we have had up to the last week or two, did not give us a chance to test the apparatus, but it has been in use frequently of late, and I am enabled to give you a few particulars of the temperature of the byre. Over the last two months, I find that the average outside readings have been a little over 40 degrees, ranging from 22 degrees, as the lowest, to 54 degrees, as the highest. The inside readings show that the cold air, after passing over the pipes, enters the byre at about 55 degrees, while the cows themselves raise the normal temperature of the byre to 60 degrees, on an average; the lowest reading of this latter shows 52 degrees, and the highest 64 degrees. The lowest figure occurs twice, and was due to very stormy weather; but, outside of this, the ventilation appears to work with remarkable regularity, keeping always near the 60 degrees."

The Saving of Soil Moisture.

[Press Bulletin, Tennessee Experiment Station.]

Capillary action, or movement of water in the soil, is due to the tension of the soil particles. If the particles are coarse, the action is weak and the soil cannot hold much water. If the particles are fine and the soil compact, the capillary action is strong, and a large amount of water will be held unless lost by evaporation.

Moisture may be retained in the soil by subsoiling, plowing, harrowing, cultivating, mulching, rolling, and by the addition of humus or decayed vegetable matter.

Subsoiling increases the depth of clayey and compact soils, and allows more water to enter them instead of running off on the surface. Subsoiling is thus an important means of preventing washing, and it also enables the roots to penetrate deeper, thus increasing the feeding area. Both spring and fall subsoiling are of advantage on stiff, heavy land.

Plowing is an important factor in saving soil moisture. The reason why lands wash so seriously is that the plowing is too shallow and it is frequently done when the soil is in an unfit condition. The plow should be run as deep as possible, being set slightly lower each year, until the top soil is eight or ten inches deep. The best plowing is that which leaves the soil in the finest state of division. Cloddy or lumpy land cannot hold a large amount of water; therefore it is important to plow when the land is neither too wet nor too dry.

Land should be harrowed after plowing before the clods become hard and difficult to crush, and the surface made as fine as possible. Frequent harrowing of lands already planted will check the loss of water. Orchards, especially those containing young trees, will be greatly benefited by harrowing at brief intervals until mid-summer. The harrow is best adapted to clayey soils. The disks should be set at such an angle that the entire surface will be tilled. As a saver of soil moisture, however, the disk harrow is considered inferior to the Acme or spring tooth harrows. If the land has been put in the proper condition early in the season, a spike tooth or smoothing harrow will be all that is needed during the summer.

The frequent cultivation of hoed crops is necessary to prevent the rapid evaporation of moisture. If the ground is sufficiently loose an implement with many small teeth should be used, as such a cultivator leaves a finer soil mulch than one with large teeth. A soil mulch three inches deep is more effective in saving moisture than one of less depth. The land should be tilled after every rain, whether the fall is heavy or light. The object of cultivation is to destroy weeds and to prevent the formation of a surface crust. This crust, if allowed to remain unbroken, favors the capillary movement of water to the surface of the ground, where the moisture evaporates. Use the cultivator several times between rains, if the intervals are long.

Nothing is more effective as a mulch than fine soil. Straw, spoiled hay, leaves, pine needle, etc., are used to a limited extent in the culture of fruits and vegetables. These materials check evaporation, keep the soil moist and loose, and help to restore fertility.

Rolling is an advantage in preventing the loss of moisture from soils not compact enough to hold much water. The compacting of such soils by repeated rolling decreases the amount of water that passes through them and beyond the reach of roots. When the object of rolling is to save soil moisture, a tooth harrow should be used if possible after rolling, so as to form a layer of loose soil on the surface; otherwise rolling will decrease the soil moisture. The roller should be used with caution on clayey lands. The purpose of using the roller after seeding during dry weather is to compact the soil, thus increasing the capillary action, which carries the necessary amount of moisture to the seeds to cause germination. The roller is sometimes used after the plants are up, which of course favors the rise of water to the young roots.

The addition of humus to soils deficient in organic material will greatly increase their capacity for holding water. This may be supplied by using vegetable mold, cover crops, rotations, green manures and stable manures. Soil moisture may be saved by other means, but those mentioned in this bulletin are the most important.

Hot or Cold Water for Inflamed Udders.

ED. HOARD'S DAIRYMAN:—Dr. Kitchen, of New Hampshire, in last week's DAIRYMAN, asks, "Is there any reason for not doing this?" i. e., the liberal application of cold water to reduce inflammation by the shrinking of blood vessels and reduce the irritability in the parts, when treating caked udder. We don't believe in the shrinking of parts. Hot water is the only thing, it relaxes the tissue and allows the free flow of blood and lymph, thus reducing the inflammation. From an Oseopathic standpoint, the rubbing and manipulation should be to stimulate the blood and lymph flow to the udder and not necessarily from the udder; thus reducing the danger of bruising the tender parts.

Kirksville, Mo. FRED ZIMMERMAN.

HOLSTEIN CATTLE! The Choicest Milk and Butter Breed in the World. Write to Wis. Live Stock Ass'n, Appleton, Wis., U.S.A.

SHADY NOOK HERD Holstein-Friesians Choice Chester-White Pigs 2 to 8 months old, both sexes, for sale. W. R. GATES, Ripley, Jefferson Co., Wis.

Registered Holstein-Friesian Cattle. Best families of the breed. Aaggies, Waynes, De Kols, Netherlands, Pauline Pauls, Pietertjes. WM. O. JACKSON & SONS, South Bend, Ind.

HOLSTEIN-FRIESIAN CATTLE
Owned by **JONES & RANDALL, Hustisford, Wis.** 100 head to select from. From families rich in butter fat. Herd now headed by Barron Paulina De Kol. Stock for sale. Prices reasonable.

HOME FARM HERD.
Headed by Jewel of Home Farm, Sweepstakes Holstein-Friesian Bull Trans-Mississippi Exposition Omaha, Neb. Seventy-five head to select from. **W. B. BARNEY & CO., Hampton, Iowa.**

MEADOW LAWN HERD Holstein-Friesians.
Herd headed by **Sir Brookside De Kol.** Choice young stock for sale. Come and see them. C. W. HARRISON, Ringwood, McHenry Co., Ill.

HOLSTEIN-FRIESIAN BULL CALVES From advanced registery and officially tested, prize-winning dams, as high as the 21-lb. class, 70 to 76 lbs. milk from cows. Quality as well as quantity. If you want *the* best address MALCOLM H. GARDNER, Darien, Wis.

Rhinecliff, N. Y.

AYRSHIRES Finely Bred and from the very best families. Stock for sale, bred for milk and butter qualities. Also fine herd Chester White Swine. Correspondence solicited.
FRED TSCHUDY & SON, Monroe, Wis.

Growing Alfalfa.

Among the many excellent and valuable papers and addresses brought together by Secretary Coburn for the recent Twenty-Eighth Annual Meeting of the Kansas Board of Agriculture, was an exhaustive article treating on alfalfa, by Mr. H. D. Watson, of Kearney, Neb., giving helpful information and advice suggested by his exceedingly sucessful experience, as to the preparation of the soil, sowing of the seed, etc.

Mr. Watson is probably the most extensive alfalfa grower in the central west, having 2,800 acres of land now set in this wonderful clover.

He says, in part:

PREPARING THE SOIL.

Our land is invariably plowed in the fall, in such a manner as to leave no back or dead furrows, and as deeply as possible, using a subsoiler on all land, the surface of which is more than fifteen feet above the sheet-water that, I am told, underlies the greater portion of Nebraska. The land is left in furrow until all the frost is out of it in the spring. We then go on to it (sometimes as early as February) with a float—an implement made of oak plank. Mine is sixteen feet long. With this, we thoroughly crush and level the ground, and follow immediately with a disk harrow, going over the land as many times as may be necessary to perfectly pulverize it, with the wheels set straight in order to pack the soil as much as possible. I am so particular about the preparation of the soil that in some instances the land is disked five times. After disking, the land is dragged thoroughly, using four horses on a twenty foot harrow at least once a week on the average, or after each rain storm. This is done to prevent evaporation of the moisture which is so necessary to the growth of all vegetation, and especially this plant.

SEED PER ACRE.

Based upon the result of many tests, I invariably use twenty pounds of seed to the acre, sowing with a Cahoon seeder, ten pounds each way; that is, ten pounds to the acre is sown crossing the field in one direction, then reseeding the same land with ten pounds to the acre, crossing the field at right angles to the first sowing. I never sow oats or other grain with the alfalfa seed now, as my experience has been that the alfalfa plant requires all the moisture available in this section, and cannot afford to share this very necessary requisite to its growth with any nurse crop. The seeding is completed between April 10 and May 15. As experiments, I have seeded every month in the year, and found that the best results followed early seeding, as the young plants then receive the benefits of the spring rains.

About the middle of June, or sooner, if the weeds are large enough to shade the ground (with us the sunflower and redroot are quite rank by that time,) I mow the land, leaving the weeds to dry where they fall, as they make a very fine mulch for the alfalfa. In four or six weeks more, according to the growth of the weeds, I mow again, leaving the weeds on the ground as before. This has given me in two instances a crop of alfalfa in September of the year of seeding, although generally I have got no hay crop until the second year.

My first seeding was in alternate strips of eighty acres, one strip with one bushel of oats to the acre and the next strip without the oats. The stand on the strips sown without the oats is to-day more than twice as heavy as on those sown with oats. Two or three times since I have seeded small areas with oats, and once with barley, only to find the same result.

BLUE-GRASS WITH ALFALFA.

Hereafter, when the alfalfa is old enough, so its roots are relying for their support entirely upon the soil below that which the blue-grass roots will penetrate, I intend sowing blue-grass upon my alfalfa fields, as this will do away with the danger of bloat that has heretofore existed in pasturing alfalfa, having observed that the cattle eat liberally of the blue-grass before eating any of the alfalfa, which prevents them from consuming sufficient of the latter to injure themselves. Also, when there is a wet spring and a heavy crop of blue-grass, we invariably get a much finer quality of hay then when we have alfalfa alone.

CUTTING AND CURING.

My experience is that it should be cut as near as possible when in full bloom. Having so large an area, this necessitates cutting a portion of mine before it commences to bloom at all. No cutting is done in the morning until the dew is off, that the alfalfa may fall upon well-warmed ground. The men are employed before that time in cultivating other crops. As soon as the hay is thoroughly wilted it is raked into small windrows, from which it is gathered later by buck-rakes into stacks. As a rule there are three men on the stack, four men on the buck-rakes one man to attend the stacker, and a boy to guide the team used with the stacker. There is a large loss of leaves attending this process, and had I a small area the hay would be gathered as I was taught to cure red clover in New England, by cocking it and letting it cure in the cock, after which it was immediately hauled to the barn that it might not get wet. As it is, what hay will be necessary for the dairy cows and breeding ewes and perhaps for all of my ruminating animals, will hereafter be cured in the cock, as I am certain that the additional expense will be more than compensated by the increased value of the hay. While there is no more valuable forage for cattle, sheep, colts or hogs than well cured alfalfa, so also there is no hay which can receive greater damage from wetting. Because of this I will hereafter put as much as possible in barns and sheds. I will put the remainder in stacks, which I shall protect with stack covers, which are now manufactured for that purpose.

In regard to the feeding value there is one thing it may be well for me to tell you, particularly as it is generally understood that alfalfa makes poor horse feed, and so it does for driving horses. In July, 1894, finding myself without old hay or grain, and no corn to be had for less than sixty cents per bushel I was compelled to depend entirely upon new alfalfa hay to feed some eighty work horses for more than thirty days, during which time they were worked unusually hard, as I was trying to subdue a swamp which was, in many places, very difficult to plow. During this time the horses were maintained in their usual condition of health and flesh, although I believe it better practice to feed some grain, in connection with the alfalfa, to all horses when hard worked. Since that time I have fed all my work horses on well-cured alfalfa, choosing for this purpose cuttings when the plant was passing out of bloom, having learned that there was more protein in alfalfa cut late.

I urge the importance of great care in procuring seed, as otherwise considerable trouble may ensue.

A Good Talk on Cows From The Dairy Standpoint.

At the late Maine Dairy Conference, in Portland, Mr. Valancey E. Fuller, who will be remembered as having charge of the Jerseys at the Chicago World's Fair, made a most excellent address on "The Dairy Cow." We clip from the same the following extracts:

The modern dairy cow, as she exists to-day, is the creation of man's handiwork, a triumph of mind over matter.

In a state of nature, the cow gave but enough milk to nurture her calf for a few months, and was dry till next calving. The enormous milking machine we have to-day in our dairies is the result of careful selection, wise coupling and judicious care and handling.

She may be aptly called an artificial machine, and, being artificial, there is a strong tendency to revert back to the less desirable side of her ancestry. To produce improvement in our cows in each succeeding generation, should be the aim of every breeder and dairyman. But such improvement is not attained by chance. Eternal vigilance, judgment and patience are the price exacted by success.

Dairying and dairy ideas have changed in the past decade.

Specialties have become the necessities of the hour in that keen competition that exists in every line of business. The dairy cow has become an institution of herself. She has come to stay.

The farming community, including the dairymen, have been passing through a period of trying depression. Low prices and low

profits, and, in too many cases, no profits at all, have been the return for expenditure of labor and capital. Mark you, I do not say for expenditure of thought, labor and capital; for the thoughtful man, seeing the turn of events, usually puts his house in order to meet the exigencies of his changing conditions.

No successful dairyman, actuated by the desire for profit, can now afford to keep the general purpose cow. His pocket teaches him that the hereditary tendency to put fat on the carcass is incompatible with economy in putting milk in the pail in the last period of gestation, and that the larger carcass of necessity takes the greater quantity of feed to sustain life and to give the necessary heat to the body, after which the surplus feed is converted into products. Taking cows, therefore, of equal ability at the pail or churn, the smaller cow is the more economical in production, and economy is really the key-note to success.

For economy in dairying, the successful dairyman must have the cow, be she pure or cross bred, of a breed especially bred for the dairy. Such a one, if pure bred, possesses by inheritance the characteristics he seeks, and has the power fixed in her to transmit her own qualities to her offspring, thus fulfilling the double function of a profitable dairy cow and a breeder.

It must be manifest that if we can have our heifers come into profit at two years old, in place of three, without detriment to her future growth, we have gained one year in profit.

The custom of bringing her in when so young, in my judgment, tends to prevent the habit of putting fat on her back, and to fix in her the milking habit; if liberally fed and well cared for between her second and third year, her growth will be all that is desired.

The necessity for tenacity in milking, and the economy there is in this feature of the cow, is so apparent it seems almost superfluous that I should dwell upon it; yet, in my travels through even well established dairy districts, I find its importance is not thoroughly appreciated.

Any dairy cow worthy of the name will give a profit to her owner in the first period of lactation, but far too many cows in the last four to five months of gestation fall off so rapidly in their milk that they rob the owner of the profit they have made in the first period of lactation. Many men, owning cows giving a very large flow of milk at flush, are prone to believe they are the most profitable cows. Unless they are in the habit of weighing their milk, they do not realize that the largest milker at her flush is not always the cow that gives the greatest quantity of milk throughout the year.

Some of the most profitable cows a man can own are those which do not give so large a flow of milk immediately after calving, but which being very tenacious in their milking, give a large quantity of it throughout the year.

If you are selling cream, you must have a cow of a breed whose milk contains a large percentage of cream. Even for the milk route, the same necessity exists in towns and cities to deliver a rich milk.

Economy in production is the keynote to success and this might be considered in conjunction with, and as a part of requisite No. 1: "An animal of a breed especially bred for the purpose;" because if you have a good animal so bred, economy in production is assured.

In the earlier part of my paper I reminded you of the generally accepted axiom that a cow consumes food in proportion to her weight. I must not, however, be construed as advocating that the cow that eats the least food is the most profitable one; on the contrary, my experience teaches me a cow that can profitably consume food is the best one for dairy purposes; that is, if she will convert that food into milk after appropriating what is necessary to support her own carcass, without putting fat upon her back. A cow with a natural tendency to fatness must be avoided in the dairy.

Having considered the requisites in the profitable dairy cow, let us next see how we can acquire such. There are two ways open: By purchase or by breeding.

I am an advocate of having them bred on the farm, by means of a pure bred bull. If you have such a bull descended from a long line of large milkers and buttermakers, he ought to breed with a uniformity that will ensure you the class of animals you desire. They will be profitable to you to keep, and profitable to sell when you have too many. By raising your own stock you can sell off old cows, replace them by those of your own breeding, and thus keep cows only during the most profitable time of their life. A man who is constantly changing his cows by purchase is very liable to introduce disease into his herd.

For the characteristics of a profitable dairy cow we must seek the reverse of a beefy animal. We want a cow with a long, slim neck, thin over front shoulder and gradually widening along her barrel and belly until it forms a perfect wedge. If this be coupled with a long, deep barrel, large paunch in which to stow away her food; if she be wedge shape; if her hip bones be prominent, affording a resting place for your hat; if her thighs be flat, then you may be reasonably assured that you have the form of a cow with a natural tendency to convert her food into milk, rather than put it upon her back.

If with these characteristics, she spreads wide her legs in walking; if she has a large udder, not too fleshy, fed by large tortuous and elastic milk veins, that spring back rapidly when compressed; if she has good lung power; if her jaws are large, and she has open, well-sprung ribs, and her general conformation shows good constitution, then you may expect a deep milker.

I have found the more loosely jointed a cow is the better she is as a dairy cow.

I have often been deceived in a deep milker by her having small milk veins, but I have generally found that while they are small, they resist the pressure of the fingers, and when compressed spring back rapidly into place, showing that the veins are very active, though small.

See that your cow be provided with good storage capacity; that she is not leggy or flat-sided.

A FEW years ago, the New York State Commissioner of Agriculture, investigated the cost of oleo, and gave the following statement:

COST OF 100 POUNDS OF OLEO.

34 pounds neutral lard, 3⅞c per pound	$1.32
27 pounds oleo oil, 3½c per pound	.84½
12 pounds cotton seed oil, 4c per pound	.48
18 pounds milk, 1c per pound	.18
9 pounds salt, about 1c per pound	.08½
Trace of color	.00
100 pounds	$2.91
Tubs, per 100 pounds	.50
Tax, per 100 pounds	2.00
Cost of mixing, per 100 pounds	1.00
Net cost at Chicago, per 100 pounds	$6.41

No wonder the oleo men have millions at their disposal, and are fighting hard for a continuance of their right to sell oleo for creamery butter. It is a stake well worth contesting; but what chance has the dairyman got to compete with pure butter, against any such figures as the above?

THE LIGHT THAT SAVES.

One dark night during the siege of Santiago Harbor a Spanish Torpedo boat darted out under cover of darkness to launch its deadly missile against an American war vessel. If she had been struck she would have gone to the bottom. What saved her? Was it her big 13-inch guns? No, it was her search-light: the dazzling white beam of light that shot straight out like a sword-thrust through the darkness, revealed the approaching danger.

What is it that saves thousands of men from death every day in the year when the deadly foe of disease is creeping unsuspected upon them? It is the white light of science; the educated understanding that reveals the source of danger and indicates the exact point of attack.

While the ordinary doctor gropes around, with the feeble tallow-candle light of stereotyped, conventional, routine treatment, a physician like Dr. R. V. Pierce, of Buffalo, N. Y., instantly illuminates the subject with the clear day-light ray of practical knowledge; the irresistible search-light of advanced and life-sustaining science.

"I was afflicted for four years," says John F. Zingsheim, Esq., of No. 9 Lark St., Amsterdam, N. Y., in an earnest letter to Dr. Pierce. "My suffering was extreme and the trouble gradually increased notwithstanding the fact that I tried many different kinds of treatment. After becoming physically incapacitated and unable to work at all, and after much hesitation, I wrote you. I am very happy to state that your advice has done me great good. You advised Dr. Pierce's Golden Medical Discovery, and also his 'Pleasant Pellets.' I must here state that they have cured me. I wish to thank you most heartily for what you did for me. All suffering has vanished and I have gained about twenty-five pounds in weight. I used only one bottle of 'Golden Medical Discovery' and one vial of the 'Pellets.'"

Do not hesitate to write to Dr. Pierce. He will send confidential advice absolutely free. Send 21 one-cent stamps to cover cost of mailing only, for paper-covered copy of Dr. Pierce's Common Sense Medical Adviser. Cloth-binding ten stamps extra. Address Dr. R. V. Pierce, Buffalo, N. Y.

Sterility in Cows.

Pateley Bridge discourses at length in *Farm and Home* on this subject, which is of considerable interest to dairymen who not infrequently complain of the failure of some of their cows to breed. The writer says:—

Dr. Fleming says that "in the cow the fecundations appear to average about 79 per cent." If we may judge from the frequent complaints of failure to breed, and the number of times we see cows being sent to the bull, this estimate appears almost too large.

The two principal conditions under which farmers and dairymen complain of infertility in their animals are when heifers and cows appear periodically in season, but do not prove in calf to repeated service, and when, after calving, oestrum does not make its appearance for months together. Sometimes the defaulters are not worth the trouble and cost of saving or retaining them as breeders, but the owner is generally very much put out about it, and sometimes to have to send a really valuable animal off to the butcher as hopelessly barren, is most disheartening. As a general rule, the owner of cows or heifers which, after a fair trial, fail to produce their kind, would do well to consult an experienced veterinary surgeon and have a careful examination made.

Sterility may depend upon organic or physical causes, and may amount to permanent impotence, more particularly when congenital and located in the generative apparatus. Whether the impotence is permanent on account of some congenital deformities, or the deformity has resulted from disease, it saves time and money to be assured of the uselessness of attempts to get the animal to breed, while the examination may result in the discovery of an obstacle to successful fecundation that is removable. A cow or heifer may come in season all right, and accept service with alacrity, and yet there may be obstacles to conception that may or may not be removable. The number of diseased conditions of the generative or other organs, as well as general derangements, that may prove a bar to fecundity, are very large. They include most of the diseases causing alterations in the ovaries, fallopian tubes, uterus and vagina, and tumors of various kinds in these organs are not an infrequent cause of sterility.

The chief obstacle to generation is the existance of some abnormal condition of the cervix uteri—and this, Dr. Fleming says, is a circumstance much more common than is generally supposed. Occlusion of the os—the canal leading to the cavity of the uterus—has been recognized as a cause of sterility from the earliest times, and the occlusion may be partial or complete. In these cases the local application of belladonna is sometimes successful, while dilating the os by means of various instruments devised for the purpose often answers very well. Hypertrophy, from plastic exudation and the formation of false membranes, is a very frequent cause of sterility in the cow, particularly in those cases that prove barren after having produced one calf. Hypertrophy, disorganization or rigidity may readily follow on injuries received in parturition. It ought not to be difficult to understand that operations may easily overcome these obstacles, and those who have cows which are really worth conserving as members of the breeding herd, would do well to remember that as the removal of obstacles to generation are, in many instances, quite within the scope of surgical measures; an expert examination is a measure of economy. It will save the waste of time and cost of keep associated with keeping an animal doing nothing, and constantly sending her to the bull, whether the examination prove that the obstacle is removable or that the impotence is permanent.

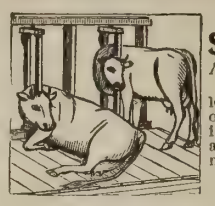
There is no doubt that sterility, like fertility, is very often a family characteristic. There are families of shy breeders, just as there are families which are regular breeders or frequent producers of twins and triplets. Very often these shy breeders are found among the aristocrats of the bovine race, the line-bred, pampered, pedigree animals. Indeed, the complaint about the heifer or the cow that is infertile is generally of a "valuable" animal—that is, valuable in point of having cost a pot of money on account of good looks and pedigree, and that would be valuable commercially if she could be persuaded to breed, and having done so, produce enough milk to bring up her calf. There are a good many owners of herds of high-bred cattle who esteem themselves fortunate if they get a calf once in two years, and this is doubtless due to infertility having become a family characteristic, as the result of long-continued exposure to artificial conditions, and high feeding of the young animals for exhibition purposes. It may be all right for the rich owner of such animals, but the ordinary farmer, who keeps cows that he may live out of them instead of living to breed cattle for exhibition purposes, cannot stand it. He wants a calf every year, and therefore these infertile, milkless animals, around which an admiring, if not particularly discriminating, public crowds at the big shows, find no place in the working herd.

The usual thing when a cow comes regularly in season is to assume that the fault lies with the bull. It may be so, for sterility in the male is not uncommon, and may arise from overwork, over-fatness, sexual debility or any of those causes mentioned as associated with the maintenance of high condition for show purposes, but the bull is very frequently changed, another is tried, sometimes three or four animals, but with no better results. It is very often only after saying nasty things about the capacity of his neighbor's bull, and doing his best to injure the animal's reputation as a sure stock-getter in the district, that the owner is driven to the conclusion that the cause of the failure resides in his own animal.

Over-fatness is a cause of infertility, and this is often associated with want of exercise and life under generally un-natural conditions. Complaints of sterility rarely come from the purely beef breeds, where very often the bull runs with the herd in the fields. But for the uncertainty associated with calving dates, there is no better method than this of insuring fertility, and if the herd is well looked after by an intelligent, painstaking man there need be very little difficulty about this. As an instance of the influence of fat, fatting foods and unnatural conditions, Lyford, an American authority, says:—"I have known a case where, of a litter of six pigs, four were fed on sugar and molasses to hurry up growth, after which all four proved barren, while the two which were turned out on ordinary feed were productive."

The association of breeding failures with the existence of epizoötic abortion is too well understood to need more than passing comment. The man who puts his aborting heifer or cow to the bull when next she appears at oestrum, without the slightest attempt at treatment, deserves nothing better than failure, but ignorance or hope causes it to be done very often—with disastrous results, as regards spreading the disease, by infecting the bull. Tuberculosis is also frequently associated with infertility, and sometimes the lesions are situated in the generative apparatus. Very often these animals are always at oestrum, and the "buller" is a recognized tuberculosis subject.

There is one point in connection with the regular appearance of oestrum that deserves mention before we leave this part of our subject. It is usual to assume that its non-appearance at the regular interval after the last service is evidence of successful fecundation, and that its re-appearance is indicative of failure. That is certainly the rule, but to both there are frequent exceptions, and we are not absolutely safe in assuming that the animal in which oestrum is absent is in calf, or that the one in which it is regularly recurrent is not. There are some animals which return to service periodically, sometimes with remarkable regularity, at the end of three weeks, long after conception, and even until close upon the period of calving.



Writing on this point some ten years ago, a correspondent of *Farm and Home* said:—We have known a cow to produce a healthy and vigorous calf scarcely a month after her last service; and we have known a cow slaughtered as barren, having come in season within the last three weeks of her life, when she had within her a pair of fine heifer calves, evidently within about six weeks of being due for birth. In these cases a stethoscope, in the hands of a veterinary practitioner, or in the hands of the owner, or any other person, if he knew where to apply it, and how to use it, would have detected the presence of living calves, by the beating of their hearts. Cows playing this trick, although not always shy breeders, are perilously liable to condemnation as such, through the owner's want of care or knowledge.

While dissenting from the statement that it is easy for anyone to determine the pregnant condition of a cow, that regularly appears in season and accepts service, I can confirm the frequency with which cows, fattened and sold to the butcher as barren, are found, when slaughtered, to be forward in calf. Every butcher of experience can tell of many such cases, and it is well to take every precaution to ascertain the condition of such animals before they are sold out to go on grass for beef, or put up to fatten at home. The cow which, having produced one or more calves, does not appear in season for months together, belongs to another class. She is none the less a nuisance than the sterile cow, or the shy breeder, which does, because she upsets the routine of management, and her place in the dairy often has to be taken by a fresh purchase, to provide for the requirements of milk contracts. There are, doubtless, many causes for the non-appearance of oestrum, but with the class of cow in question, it is due to the fact that she is producing milk. This is proved, if proof were needed beyond that afforded by experience of what happens in other animals, by such cows breeding readily when dried off. It is quite a common thing for the owner to keep waiting and waiting for the cow to come in season, without any appearance of it, until she begins to fail in her milk, when he wants one in full profit, and she is sold as she is, or dried off and disposed of as barren. About the first thing she does then, is to come bulling in her new owner's hands, and make herself a nuisance that way. It is not at all uncommon for a dairyman to buy back the cow forward in-calf he sold empty some months before, and the only secret in the matter is, that she failed with him because she was in milk, and succeeded with the other man, because she came in season as soon as lactation ceased. Medical men meet with many such cases in their practice, especially among the poor, where large families are unwelcome.

There is no real remedy in these cases—it is purely a question of profit and loss. Does it pay to retain a cow doing nothing to earn her keep during the whole period of gestation? Most people think not, but there seems no alternative but to do so, or sell the animal out when her milk yield no longer comes up to the standard of profit. All these difficulties, coupled with lack of convenience for keeping "drapes," make people willing to pay high prices for cows that have just calved or that are on the point of calving, with the intention of selling them out as soon as their milk yield falls below a certain point. But even the men who supply this market cannot afford to keep cows doing nothing but carry a calf and no one wants animals that are dry for more than a month or six weeks before they calve again. Failure to appear in season, while in full milk, seems a trouble that is very much on the increase, and probably will continue to increase with the cultivation of the milking habit.

There is one point worthy of note in connection with the cases. Very often the cows appear in season once, just after parturition, and if that is missed the opportunity for service does not occur again while milking continues. Very often the period is allowed to pass, because the owner considers it too close on the birth of the previous calf, or perhaps because he wants her to come in at a particular time, which would not accord with the convenience of the cow. There is, no doubt, a good deal in the popular notion that if the first period of oestrum after parturition

KIDNEY TROUBLE Is a deceptive disease—thousands have it and don't know it. If you want quick results you can make no mistake by using Dr. Kilmer's Swamp-Root, the great kidney remedy. At druggists in fifty cent and dollar sizes. Sample bottle by mail free, also pamphlet telling you how to find out if you have kidney trouble.

is missed, the opportunity may not occur again for some time, and also in the notion that it is the most certain as regards conception. The cow, ass, sheep and mare, it is believed will copulate with greater certainty of success on the ninth day after parturition, than at any other time, and there seems a good deal of warrant for it. It is for this class of irregular breeders that the great demand for recipes to bring them in occurs.

I am no believer in drugs for this purpose, for these "remedies," known technically as aphrodisiacs are most uncertain in their action, and special stimulants, given in doses, calculated to be effective, are not wholly free from danger. That most frequently employed cantharides—has in large doses, a most deleterious action on the kidneys, and is a powerful irritant poison. Other aphrodisiacs—perchloride of iron, nux vomica, phosphorus, and the peppers— are uncertain, or only useful in cases where there is debility, and blood and nerve tonics are indicated. So called "procreative powders" are largely advertised at high prices as certain to be effective, but it is always well to take a liberal discount off the claims of the proprietary medicine man. An example of such medicine is: Powdered cantharides, 2 drachms; aniseed, grains of paradise, bayberries, and pimento, all freshly powdered, of each one ounce. Give in a quart of milk two hours before food. This formula was given to me as a great favor by an old man who declared it would certainly cause the cow to come fit in 10 days. I have never ventured to try it; but a single dose could hardly do harm, and anyone in difficulties might put it to the test.

Power for a Silo Cutter.

ED. HOARD'S DAIRYMAN:—Will say to Buff Jersey that we use a 17 inch cutter, 28 foot elevator and 18 foot conveyer. Engine 100 feet from cutter, power transmitted with ¾ inch Manila rope. For eight or nine years we used a 5 H. P. engine, 6 H. P. boiler and it worked well. The engine was an old one, and four years ago we put in a new 8 H. P., still using the old boiler and feeding engine with one inch pipe, and have all the power we need. Rope lasts from five to six years, cutting from 400 to 500 tons yearly, besides grinding.

I have a neighbor who uses same size cutter, 30 to 35 feet carrier; 6 H. P. engine located fully 125 feet from cutter; transmits power with rope, and as he has used it nine or ten years, and continues, I conclude it gives him satisfaction. T. BACON.

Lake Co., Ill.

A Good Law.

New York dealers find that since the enforcement of the law which requires process butter to be marked "renovated," they can not handle it at all. People do not want butter that they know has been made out of what would otherwise be unsalable, no matter how clean it may appear after renovation. —*New York Farmer.*

The above quotation well illustrates the beneficial effects of such food laws as place dishonest greed and sophistication in the light of a plain and truthful statement. What all these dealers and manufacturers of oleo, and other deceptive substitutes dread, is publicity.

Butter, Cream or Cheese.

In these times of close competition in dairying, to be master in his business, one must know how much milk will yield, made up into various products, when their market prices are such as to warrant a diversity. When milk, testing 4 per cent, sells for five cents a quart, and skim milk is worth twenty cents per hundred pounds for feeding, it is bringing the equivalent of forty cents per pound for butter. One hundred pounds of milk testing 4 per cent fat would yield, on the average, 4.5 pounds of butter. In one hundred pounds of milk there are about forty quarts. This, sold at five cents per quart, would bring $2, and taking out twenty cents, price of skim milk, if butter were made, we see that 4.5 pounds of butter must sell for $1.80, or forty cents per pound. In a similar way, we see that sixteen cents per quart for cream testing 20 per cent fat is the equivalent of 29.3 cents for butter.

The yield of butter is estimated in many creameries by adding one-eighth to the butter fat; the yield of green cheese by multiplying the fat by 2.7, and that of cured cheese by multiplying by 2.6. This estimate is based upon milk containing about 3.7 per cent fat, however, and the richer the milk the greater the yield from a given amount.

A hundred pounds of milk testing 4 per cent fat, will yield about 4.5 pounds of butter, or 10.8 pounds of cheese. If it costs three cents per pound to make the butter, and one and a half cents per pound to make cheese, eighteen cents per pound for butter will be equivalent of 7.6 cents per pound for cheese.

Such problems as the above, the up-to-date creamery man must solve readily, and then turn his milk into the most profitable channel.—PROF. H. HAYWARD, of Pennsylvania Experiment Station.

"Profits Scarcely Visible to the Naked Eye".

"What Shall We do to be Saved".

The above titles are the remarks made by a Kansas creamery patron. His year's record shows that he milked eight cows, which yielded him an average of 131 pounds of butter fat, for which he received $19.63. His cows consisted of three Jerseys and five mixed Holsteins and Short-horns. These he bred either to a Short-horn or Hereford bull. His winter grain was corn and oats, and his roughness clover hay, millet and corn fodder. Until prices for butter fat improve he expects to get the most profit from "good calves and fat cows".

From the above it will be seen that this patron is very changeable. First he runs to dairy stock, and as soon as the price of butter fat falls a little he changes to beef. This changing from milk to beef and from beef back to milk is enough to ruin any herd. A person familiar with the laws of breeding knows that a cross of two distinct breeds is liable to produce offspring with characters foreign to both. We sometimes hear it remarked that if we should cross a Holstein on a Jersey the offspring would be a cow that would yield the quantity of the Holstein and the quality of the Jersey. The result is much more apt to be a cow with the quantity of the Jersey and the quality of the Holstein.

This is an age of specialties, and the man who makes the greatest success is the one who selects a specialty and sticks to it. The successful dairyman is the man who stays by his cows, even though the price of butter fat should be low for a season. If he should attempt to change to beef it would take several years to do so, and by that time the price of butter fat may be high, while his cows are ruined for dairy purposes. When butter fat is low is just the time to push the dairy business, for sooner or later there will be a reaction, and the man who is ready is the one to reap the profits.

The patron realized for butter fat $19.63 per cow, per annum. The agricultural college scrub herd that had been pushed along dairy lines brought an average of $37.75 per annum. This difference of $18.12 per cow is what would have been visible to the naked eye had his cows been handled as the agricultural college cows were handled. "What shall we do to be saved?" Settle upon some definite line of work, study the business in all the details, find out what others are doing in the same lines, make it a hobby, and, above all, stick to it. D. H. O.

Kansas Experiment Station.

Feeding Fat Into Milk.

We are in receipt of a letter from an eastern subscriber, in which he says: "*The Practical Dairyman* asserts that fat cannot be fed into milk. This is contrary, I think, to the position taken by the Massachusetts Experiment Station. In one of the bulletins of that station, I believe, it was asserted that both protein and fat would increase the fat in milk."

Our correspondent is both right and wrong. In looking over the bulletins of that station, we find one in which occurs the following: "Feed has very little, if any, effect upon the quality of milk. By quality we refer to the per cent or amount of total solid matter in the milk. It is a well-recognized fact that some feeds affect the flavor of milk, and possibly, to a slight extent, its color. Feeds rich in protein have a tendency to slightly increase the percentage of fat in case of some cows; the same can be said of feeds rich in fat. This increase is probably only temporary, however, the milk gradually coming back to its normal composition. Animals very thin in flesh and insufficiently fed, if brought into good condition by proper feed, will probably yield milk of rather better quality. The improvement in quality will not, as a rule, be very marked. The milk-producing function is, to a large extent, under the control of the nervous system. Any influence that disturbs the quiet or normal condition of the animal, be it rough usage, extremes of temperature, exposure to rain, etc., will have its effects upon the quality of the milk. On the other hand, plenty of good feed increases the quantity of milk until the animal reaches her maximum production. What has been said with regard to the influence of feed upon the quality of milk is equally true relative to the amount of butter that can be made from a given quantity of milk. No method of feeding has yet been discovered that so improves the quality of the milk as to make a given quantity of milk produce more butter at one time than another. The quality of milk varies during the different stages of lactation, but this is entirely independent of the influence of feed. The above statements are based on the teachings of carefully conducted experiments. They are contrary to the general belief that the better the animal is fed the better the quality of the milk produced."

There is no criticism to make upon this position, except that it is pretty well settled that when there is an increase of fat, seemingly as a result of a change of feed, it really can not be traced to the feed. As some have expressed it, "it probably was owing to some other cause." If the food could accomplish this, why should not the better quality continue as long as the feed continued? It never has, so far as we are conversant with experiments in that line.—*Practical Dairyman.*

Sow More Clover.

At a recent Canadian meeting of farmers the writer of this was much impressed with the address of Professor Saunders in regard to the importance of the clover crop and its relation to the maintenance of soil fertility. It was so greatly at variance with the old-time doctrine that it sounded like a new revelation. The old doctrine, says a writer, in New York *Tribune*, was that clover took all its properties from the soil, and this address was, that latest investigation revealed that about all of the nitrogen was caught from the air, and, while there was no new gifts of potash and phosphoric acid, the clover plant gathered up stores of the latent materials of these and gave them back to the soil in an assimilated form for the succeeding crop, which really amounts to a new supply. Another thing which was valuable, if it is confirmed, is that a crop of clover left upon the ground and not plowed under until spring would, as a mulch, add a large percentage of nitrogen to the soil by this covering, in addition to the stored nitrogen gathered by the plant during its growth. It was also noticed that the figures given by the Canadian investigations run very even with those figured out by Professor Roberts at Cornell, and show that clover is clover wherever it can be grown. The figures show that the plant food secured by a full crop of clover was about an average of 125 pounds of nitrogen an acre, 35 pounds of phosphoric acid and about 120 pounds of potash, or about $22 worth, as purchased as high-grade fertilizers. Clover improves the land, as does no other crop, in texture, and supplies other plants with exactly the food they require, so that when one has a clover crop to plow under, the succeeding crop is assured. One of the things about the plant food supplied to following crops by clover, is its availability and the readiness with which it can be assimilated by the plants, while the farmer has little foreknowledge of what the effect of a purchased fertilizer will be. The fertilizing ingredients of a commercial fertilizer are not always in available forms for the plants, and possibly may be in quite as inert a condition as the plant food may be, in soil depleted of its fertility by cropping. The nitrogen in dried blood, nitrate of soda and the like, is quickly available, but in wool waste, hair, hoofs and leather scrap, it is so slowly disintegrated that the plant would starve before it could get a meal of it. Materials sold in fertilizers may show high percentages of plant food, and still be almost worthless as food for plants, owing to the fixed character of the material, which even sulphuric acid cannot liberate; but the clover plant is a fertilizing agent whose goods are as represented, are in available form, and need no liberating reagent to set them free, beyond the natural ferments of the soil. The cheap price of clover seed this season, and the possibilities of sowing it with all small grains, and as a catch crop in the corn, and a special crop by itself, should stimulate all farmers to sow clover with an unstinting hand, and return as nearly as possible to nature's methods of restoring and building of soils. Possibly the soil, after several successive rotations of crops and clover, would need to be reinforced with an application of South Carolina acidulated rock and some muriate, or sulphate of potash. Then the rotation will go on again, as the nitrogen is all the time being supplied through the agency of the clover. Peas, rich in nitrogen, come in as a wonderful help as a catch crop, as they can be grown in fifty days, and are valuable aids in supplying plant food. Their mechanical effect upon the soil is second only to clover. Try it this year and see if 75 cents' worth of clover seed, put on an acre, will not result as beneficially as would a ton to the acre of $22 phosphate, and with these advantages: The clover fertility would last two or three years, instead of only one, and the mechanical effect is far superior to purchased plant food; and, lastly, there will be $21 difference in the expense account.—*Prairie Farmer.*

CONCERNING OUR ADVERTISERS.

MANILA HEMP NOT HEMP AT ALL.

One of the most valuable products of our new possessions, the Philippine Islands, is what is called Manila hemp, which is not hemp at all, but is obtained from a plant belonging to the plantain family. Trees of three years' growth yield only about two-thirds of a pound of fibre each; a bale of 270 pounds, therefore, represents the three years production of about 400 trees. The Deering twine mills at Chicago consume an immense amount of this fibre, manufacturing one-third of all the binder twine used in America.

Official Tests of Holstein-Friesian Cows, from January 1, 1899 to March 1, 1899.

ED. HOARD'S DAIRYMAN:—These tests are for seven consecutive days and are supervised by officers of agricultural colleges and experiment stations, or by persons vouched for, by such officers. The amounts of butter fat are determined by the Babcock test and the amounts of butter are calculated on the basis of 80% fat to a pound of butter, the rule established at the Chicago World's Fair.

Adventuress 6452; age 9 years, 8 months, 9 days; amount of milk, 409.7 pounds; amount of butter, 18 pounds, 11.1 ounces.

Belle Korndyke 13913; age 10 years, 9 months, 13 days; amount of milk, 509.8 pounds; amount of butter, 25 pounds, 12.3 ounces.

Clothilde Artis Belle 34740; age 5 years, 9 months, 23 days; amount of milk, 466.8 pounds; amount of butter, 20 pounds, 6 ounces.

Duchess of Beechwood 35703; age 5 years, 7 months; amount of milk, 397.1 pounds; amount of butter, 16 pounds, 8.7 ounces, in an economic test; cost of butter, 7.07 cents per pound.

Duchess Ormsby 16004; age 9 years, 10 months, 14 days; amount of milk, 359.9 pounds; amount of butter, 24 pounds, 4.4 ounces.

Kitty Clyde's 2d Coral 33958; age 6 years, 4 months, 19 days; amount of milk, 482.5 pounds; amount of butter, 24 pounds, 6 ounces.

Leaffy 38708; age 6 years, 3 months, 8 days; amount of milk, 378.9 pounds; amount of butter, 17 pounds, 12.5 ounces.

Nancy Dewdrop 2d's Hollander 36584; age 6 years, 1 month 20 days; amount of milk, 421.3 pounds; amount of butter, 19 pounds, 8.9 ounces.

Nattie Maid 33314; age 5 years, 9 months, 6 days; amount of milk, 467.4 pounds; amount of butter, 18 pounds, 10.7 ounces.

Orrice 5th 34662; age 5 years, 10 months, 7 days; amount of milk, 331.6 pounds; amount of butter, 15 pounds, 13.3 ounces.

Princess Penrosa 12711; age 10 years, 3 months, 9 days; amount of milk, 409.2 pounds; amount of butter, 19 pounds, 13.1 ounces.

Springvale Duchess 33986; age 6 years, 2 months; amount of milk, 376.4 pounds; amount of butter, 16 pounds, 12.3 ounces, in an economic test; cost of butter, 6.37 cents per pound.

Wing Vergens 9824; age 10 years, 11 months, 25 days; amount of milk, 424.7 pounds; amount of butter, 18 pounds, 2 ounces.

Johanna DeKol 36478; age 4 years, 8 months, 16 days; amount of milk, 437.6 pounds; amount of butter, 20 pounds, 4.4 ounces, in an economic test; cost of butter, 6.46 cents per pound.

Piebe Queen 2d 37957; age 4 years, 9 months, 17 days; amount of milk, 320.4 pounds; amount of butter, 15 pounds, 4.1 ounces.

Jennie Marie 45219; age 4 years, 4 months, 6 days; amount of milk, 322.4 pounds; amount of butter, 15 pounds, 1.5 ounces.

Nannette 3d's Pledge 2d 39518; age 3 years, 10 months, 1 day; amount of milk, 412.7 pounds; amount of butter, 17 pounds, 5.9 ounces.

Piebe Queen 3d 39580; age 3 years, 10 months, 13 days; amount of milk, 310.7 pounds; amount of butter, 15 pounds, 5.3 ounces.

Ginger 40757; age 3 years, 3 months, 19 days; amount of milk, 541.8 pounds; amount of butter, 20 pounds, 6 ounces

Pieterje Hengerveld Lady DeKol 41977; age 2 years, 7 months, 24 days; amount of milk, 308.1 pounds; amount of butter, 14 pounds, 2.1 ounces.

We Repeat 41016; age 2 years, 10 months, 3 days; amount of milk, 301.6 pounds; amount of butter, 12 pounds, 5.7 ounces.

Johanna DeKol 2d 42168; age 2 years, 27 days; amount of milk, 348.4 pounds; amount of butter, 16 pounds, 0.8 ounces, in an economic test; cost of butter, 5.7 cents per pound.

Johanna DePauline 42169; age 2 years, 2 months, 8 days; amount of milk, 311.9 pounds; amount of butter, 14 pounds, 0.7 ounces, in an economic test; cost of butter, 6.8 cents per pound.

Natsey's Lady Baker 41879; age 2 years, 2 months, 24 days; amount of milk, 303.3 pounds; amount of butter, 12 pounds, 12.4 ounces.

Paula Parana 43512; age 1 year, 11 months; amount of milk 202 pounds; amount of butter, 10 pounds, 1 ounce.

Paula Rixa 43514; age 1 year, 10 months, 18 days; amount of milk, 255.5 pounds; amount of butter, 12 pounds, 2.7 ounces, in an economic test; cost of butter, 7.95 cents per pound.

Piebe Queen 2d's Princess 45006; age 1 year, 8 months, 13 days; amount of milk, 253.3 pounds; amount of butter, 11 pounds, 2.7 ounces.

Wimpje's Albino DeKol 42754; age 2 years, 4 months, 28 days; amount of milk, 294.4 pounds; amount of butter, 12 pounds, 12.3 ounces.—S. HOXIE, Sup't Advanced Registry, Holstein-Friesian Association of America, Yorkville, N. Y.

Drying Off Cows and Calving Time.

It is not unusual to find a cow which shows no inclination to dry off at any time after dropping her first or second calf. Such an animal shows an excellent dairy trait—persistence in the milking habit—but it is doubtful if continous milking is profitable. Better results are believed to be obtained from cows which are inclined to take an annual rest, if not too long. A month is long enough; three weeks will do in most cases, and six weeks should be the longest time encouraged or allowed for a cow to be dry before calving. An accurate record of service by the bull is essential to preparations for drying off cows at the right time. A table should be kept of the dates when cows of the herd are successively due to calve, with notes as to milking habit of every one. When the time comes for drying off a cow the grain food should be gradually withdrawn. This may of itself cause milk to cease forming. If not, omit one milking a day, then milk once in two days, and thus extend the drying period over two weeks. The udder must be watched, and if any hardening or unnatural heat is shown regular milking must be resumed. If the cow continues to secrete milk it must be drawn. No cow should be forced to "go dry" against manifestly natural resistance to so doing. On the other hand, if an unpleasantly pungent or "smoky" taste appears in a cow's milk, she may as well be dried at once, regardless of dates, as her milk will not be good until she is fresh again.

The dry cow may be kept on pasture alone, not too luxuriant, or on a low stable diet, mainly, of coarse forage, until about two weeks before calving. Yet the ration, while comparatively "wide," should be nutritious, and it should include a share of succulent food—roots or silage. Then a slow but steady increase of feeding may proceed, of a nourishing, cool and laxative kind, so as to become narrower in ratio. Wheat bran is a good material to use at this time, but new-process linseed meal is better. Experience has led the writer to endeavor to have his cows calve on an up grade, as it were, while daily gaining in strength and vigor, on a judiciously prepared, nourishing diet, but without high feeding or plethora. A week before calving remove the cow to a roomy, comfortable, quiet box stall, preferably within hearing of the herd, if not in sight. Be sure the bowels are quite loose and moving freely for two days before calving. Watch for the event, but do not disturb the cow or interfere unless something goes wrong or assistance is manifestly necessary.—*Primrose Bulletin.*

AMERICAN STEEL & WIRE CO. General Offices: CHICAGO, ILL.

EVERY DAY IN THE YEAR. MOST MEN will pay $125 for a twine binder or a corn binder, machines that can only be used a few days in the entire year, and think nothing of it.

The Kemp Manure Spreader costs much less than that, and can be used successfully every day in the year. It will earn the interest on the money every day it is used. Spreads all kinds of fine and coarse manure, wood ashes, lime, salt, etc. Spreads broadcast or drills in the row. We make a special drilling attachment for this machine, which is of unusual value to tobacco and cotton planters and southern truck farmers. Splendid new catalogue FREE. Tells all about it.

Kemp & Burpee Mfg. Co., Box 46, Syracuse, N. Y.

Paint your Home!

You know it needs it.

It is economy to paint once in so often as it prevents sun and rain from eating the life out of the wood.

Our paint costs no more than the ordinary kind but is vastly superior in quality and goes further.

Send us the number of square feet to be covered and we will tell you the cost. Write at once.

The Minnesota Linseed Oil Paint Co., Minneapolis, Minn.
Oldest and Largest Paint and Oil Manufacturers in the Northwest.

THE NEW BOOK
Feeds and Feeding

By Prof. W. A. HENRY,

Wisconsin Experiment Station.

This book should be in the hands of every stock feeder in the country. Every reader of HOARD'S DAIRYMAN ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehensive from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be referred to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price, $2.00.

A Perfect Milk Wagon

On a Perfect . . . Short Turning Gear

WE make the only drop center wagon that has a self-balancing, short turning gear. All parts are wrought iron forgings. It is so plain and simple that it can't get out of order and if any part should break, any country blacksmith can easily repair it. All other wagons of this kind have complicated gears, and mostly made of cast iron.

Write us for our Catalogue, which fully illustrates and describes this wagon and 10 other styles.

THE O. ARMLEDER CO., Cincinnati, Ohio.

THE ONLY LOW-DOWN

Short Turn, Straight Bottom, Short Coupled, Light Draft Wagon on the Market.

20 INCHES FROM GROUND to bottom of body. Will turn as short as any cut under reach wagon. Strong construction, nicely finished. Send for Catalogue, prices and terms. Wagons for carrying Bottled Milk a specialty.

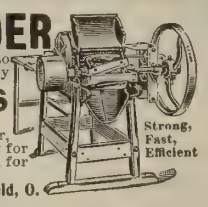
SMALLEY MFG. COMPANY, SOLE MAKERS, **MANITOWOC, WIS.**

MAKE ONLY SWEET ENSILAGE

Ever since the ensilage system has been introduced in this country it has been the ambition and effort of siloists to ***produce sweet ensilage.*** The making of sweet ensilage depends principally upon two things—***1st.*** the use of a well matured crop and ***2nd.*** upon low fermentation. Granting the maturity of the crop, shredded ensilage makes the sweetest ensilage. The reasons are, that shredded material is of a nature that makes it pack much more closely in the silo. That means exclusion of air; there can be no extreme fermentation and consequent development of acid without the free action of the air. ***Shredded ensilage possesses other advantages in addition to its sweetness:—*** it is eaten with great avidity by animals, being a long, soft substance and free from any sharp angles and corners to cut or lacerate the mouth and gums; it is therefore fed with less waste.



The best way to Shred Ensilage is with the

St. Albans Ensilage and Fodder Shredder.

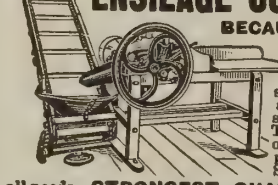
It is the Original Shredding Machine and all other so-called shredders are merely imitations of this one. ***It will certainly pay you*** to look into the merits of this proposition and machine before buying. We mail free a pamphlet on the subject.

ST. ALBANS FOUNDRY CO., ST. ALBANS, VT.

CORN FODDER

is equal in feeding value to the best hay when prepared by

THE ROSS ENSILAGE MACHINERY.



Strong, Fast, Efficient

Cuts ensilage, corn fodder, hay, &c., for **feed**, and straw for **baling and bedding.** Send for free catalogue No. 7

Revolutions vs. Efficiency.

25-inch Danish-Weston Separator.	First made in 1884. Now out of use. Very dangerous. Many fatal accidents. Very inefficient.	Revolutions 2500 per minute.
15-inch Danish-Weston Separator.	First made in 1886. Nearly out of use. Extremely dangerous. Inefficient.	Revolutions 4500 per minute.
Improved Danish-Weston Separator.	First made in 1890. Used considerably in some localities. Medium efficiency.	Revolutions 5500 per minute.
Disc and Cone Separotors.	First made about 1892. Largely used. Very dangerous. Efficient when in perfect order.	Revolutions 6500 per minute.
Sharples Improved Russian Separator.	First made in 1894. Extensively used. Entirely safe. Efficient under proper conditions.	Revolutions 8000 per minute.
Sharples Tubular.	First made in 1898. Fast coming into extensive use Absolutely safe Unequalled in efficiency.	Revolutions 23000 per minute.

The Sharples Tubular Separator

The history of cream separators is that efficiency, durability, and desirability keep pace with increasing revolutions per minute. Increaced revolutions does not mean increased speed. A slight calculation will show that circumferential speed of all above named separators is between 20000 and 25000 ft. per minute.

Increased revolutions means increased centrifugal force; hence a smaller bowl gives more safety, more efficiency, and a finer produce.

Reading notices, 50 cents per line (nonpariel measure) each insertion

The first fine under the new Minnesota Renovated Butter law was inflicted in Minneapolis recently. A. D. Housan was fined $25 for not labelling properly the renovated butter he was manufacturing. Renovated butter, oleomargarine and all other attempts to impose doctored substitutes upon consumers, find little favor in Minnesota.

Creamery patrons are beginning to see that their interest lies in supplying pure milk and not endeavoring to place all responsibility for poor butter on the shoulders of the buttermaker.

The directors of the Richland (Ill.) Co-operative Creamery Co. have adopted the following resolutions:

Resolved.—That no milk shall be sent or brought to said factory that is taken from a cow twenty days before due to calving and sooner than eight days after calving.

Resolved.—That any person found guilty of sending or bringing milk to said creamery that is known to be impure or unwholesome in any way will be prosecuted to the extent of the law, and such party's milk refused at said creamery.

MISSIONARY WANTED.

A farm paper, published in an eastern state, devotes half a column of its editorial page to an article on the "Five Minute Churn." It describes the action of the machine as follows:

It consists of forcing an air current through the milk, which, combined with the centrifugal motion of the milk, causes a reaction of the phosphates and oxidation of the casein. This liberates and gathers the fat oils as butter without a chemical change in the milk.

It seems strange that a reputable farm paper should descend to printing such a mess of nonsense as the above, but not being content with a single explanation, it repeats as follows:

The churning, the separation of the fat, is caused by a current of air forced through the cream which oxidizes the coverings of the fat globules.

No details are given as to the thoroughness of the work or analyses of the buttermilk, but the "butter was laid on a board for half an hour to drain, after which it was ready to put in a crock for use without further working."

If the above is an example of eastern dairy knowledge, as shown in the columns of a prominent farm paper, then there is a decided call for missionary work in, at least, one editorial office.

It is no wonder that fakes and butter nostrums flourish, when such is the quality of dairy knowledge furnished by farm papers.

THE TUBERCULOSIS QUESTION.

The communication from Prof. Beach, printed elsewhere in this issue, as well as various "news" items in the daily papers, brings the tuberculosis question into greater prominence than it has had for some time. The "scare" that was developed some four or five years ago, and was so industriously promoted by Dr. Ernst, of Massachusetts, and others, had measurably subsided under the logic of experience and scientific experiments, both in this country and in Europe, but recently certain boards of health, having little or nothing else to do whereby they could attract attention to themselves, have re-opened the question of the danger of infection from the milk and meat of animals which react to the tuberculin test.

The position of Hoard's Dairyman on this question is well known, and has been consistent and conservative from the first. It accepts every fact and every logical conclusion from these facts. When the evidence is conflicting it endeavors to weigh the same dispassionately, and discriminate between that which rests upon established facts and that which is mere opinion.

One of the primary facts, established by the concurrent testimony of the tables of mortality and individual observation is, that human tuberculosis is on the decrease, notwithstanding there has been both actually and relatively large increase in the consumption of both meat and milk. This does not prove that meat and milk from tuberculous animals may not be infectious, but it does afford a sufficient basis for insisting that there is no occasion for a panic, and no necessity for resorting to heroic measures.

Another primary fact is that the statement so freely made and so frequently repeated to the effect that bovine tuberculosis has largely increased within recent years, and this more especially among dairy animals, has not so much as the shadow of a foundation upon which to rest. Ten years ago, there was practically no way of determining whether an animal was tuberculous, unless in the very last stages of the disease; to-day with the tuberculin test, the existence of a single tubercle, no matter where located, whether in the lungs, the abdomen, or the knee joint, suffices to set up a reaction and thereby assign the animal to the infected list, although she may live to full age, and never exhibit any physical symptoms of the disease.

There are no more stars or comets in the heavens to-day than there were a thousand years ago, but the telescope has multiplied our knowledge of them a thousand fold or more. It is somewhat so with bovine tuberculosis. Whether the disease is more prevalent now, than it was years ago, we cannot determine, because the means of discovering and detecting it have been so marvelously increased.

Moreover, we want to know something more definite about the infectiousness of milk from tuberculous cows. If, as Prof. Beach suggests, all these cases in the Storrs College Herd developed from one purchased animal, and in a single year, it is evident that the danger of infection from contact outweighs that from using the milk, and raises the presumption that in not a few of the reported cases, where it is alleged that the disease had its origin in the milk, there have been too hasty conclusions.

JERSEY CALVES IN CLOVER.

Property of Milo C. Vosburg, Fort Atkinson, Wis.

That the disease does exist, and that it is a menace to our herds, is abundantly exemplified in the experience with the Storrs College Herd. It is also shown that utmost care does not suffice to exclude its ravages, and that so far as is yet known, there can be no guaranty against its introduction and development. In other words, there is much yet to learn, and it is the duty of our experiment stations to become the pioneers in the search for the facts concerning tuberculosis.

SUSIE THE MILK MAID, AT EIGHTEEN MONTHS.

Property of C. T. Kaler, Olympia, Neb.

It is fortunate for all of us that Storrs College has been forced to take up this duty, and that it has had the manly courage not to shrink or turn aside. We are told on every hand, that healthy offspring can be raised from reacting dams and sires. If this be true,—and we believe it is—it is important that the evidence should be not simply conclusive, but so overwhelming that a denial or even suspicion should be as impossible as it is to contest the multiplication table.

What the world needs is more facts, and fewer theories and opinions. The Wisconsin Experiment Station once had a serious outbreak of tuberculosis in its herd, and in excess of zeal slaughtered every animal. Sometime later it got permission to experiment with a private herd, and the results were so encouraging that it purchased the infected herd that it might have it at closer range, and under more definite control. If experiments in Wisconsin and Connecticut produce similar results, we shall begin to have some facts that it will be safe to tie to.

DIFFERENCES IN PATRONS.

The great range in the price received by patrons for their milk, in the same creamery, was well illustrated by the dividend paid by the Valley Falls Creamery at Himsburgh, Vermont, for the month of March. The highest test of any patron for the month was 5.125; the highest price paid any patron was $1.20½; the lowest test of any patron for the month was 3.30; the lowest price paid any patron was 77½ cents; the average test of all patrons for the month was 3.77; the average number of pounds of milk received per day was 23,217; whole number of pounds of milk was 719,739.

At the Cabot Creamery the highest test, for any patron for that month, was 6.30; the lowest test for any patron was 3.40. Here is a difference of nearly 100 per cent. It is these marked differences in the quality of milk, and also in the amount of money received for 100 pounds of milk, that show the necessity for a much better state of dairy knowledge among the great mass of dairy farmers.

J. J. Clark, a graduate of the Wisconsin Dairy School, has built and runs a creamery, near Berlin, Wisconsin, and is withal a dairyman. Notwithstanding he was reared and lives in a community much given to the general-purpose heresy, experience has taught him that success in dairying, as in any other business, calls for singleness of purpose, and tools, implements, machines and animals adapted to that purpose. To this end he has recently purchased, of Mr. H. C. Taylor, his third Jersey bull, a grandson of Diploma, (sire of Merry Maiden) and of Recorder (son of Brown Bessie.)

THERE has been no rain in some portions of Massachusetts in 83 days and as a consequence a milk famine is threatened.

BORAX, boracic acid and nitrate of potash, cost from six to ten cents per pound. When made into "Preservaline," and put up in a nicely colored box, they retail at over twenty cents per pound. From the above figures, we can judge how perfectly disinterested is the advice of the preservative men, to use Preservaline, and how absolutely sure they are, that it is harmless.

DIVIDE AND CONQUER.

This was the maxim of the ancient Romans, and by following it they were enabled to conquer the world. Artifice, fraud, false pretence, money and sometimes force were used to divide their opponents and set them to warring with each other, when Rome would step in and subdue them, one after the other.

The oleomargarine combine of to-day is trying to follow the same tactics. In its estimation, all it has to do to break down the efforts of the National Dairy Union to secure national legislation against the great fraud, is to set certain men and papers (that claim to be exponents of dairy sentiment) at the work of maligning the officers of the Union. It is a silly conceit, and only outmatched by the silliness of those who are thus lending themselves to do this dirty work.

No paper can make, or long mar the dairy cause.

All frauds, whether oleomargarine, process butter or anything which pretends to be what it is not, (including the men and papers aforesaid) must eventually come under public ban, when the public gets to know them as they are.

THE FILLED CHEESE LAW.

The result of the national law for the regulation of filled cheese is beginning to be evident.

In 1893 there were about 150 factories in Wisconsin making 8,000,000 pounds of filled cheese per year. Most of this cheese was exported with the brand "Wisconsin Full Cream Cheese." The result was that Wisconsin cheese received a reputation that it will take years to overcome. The same is true of Illinois, where 12,000,000 pounds were manufactured annually.

The government reports just issued, show that for the period of two years, since the law was passed, there has been manufactured in the United States only 3,065,000 pounds of filled cheese, as against an annual product, previous to 1896, of from 12,000,000 to 14,000,000 pounds. Of the 3,065,000 pounds manufactured since the law was passed, only 205,000 have been exported. There was a falling off in the production of filled cheese in this country from 1,663,067 pounds for the fiscal year ending June, 1897, to 1,402,861 pounds for the fiscal year ending June, 1898. All the filled cheese now manufactured is produced in Illinois, Louisiana, Maryland and New Jersey, and from the tax on it the government has received a revenue in the past year, amounting to $16,518.

It requires no prophet to tell that the law has been of great benefit to every dairy state, and that the suppression of the fraud has and will continue to benefit the dairy interests of the country.

Is There Waste in This Style of Feeding?

A California Inquiry.

ED. HOARD'S DAIRYMAN:—Mr. Argol's query in your June 2nd edition as to "what kind of fellows live west of the Rockies any how?" leads me to ask wherein my present ration is wrong. I am milking 480 cows, mostly heavy Holsteins and grades for the city milk trade. These cows get, during our dry season, practically no pasturage. The ration they are now getting is all the alfalfa hay they will eat without waste(30 to 35 lbs.), bran 5 lbs., corn meal 2 lbs., and oil meal 1 lb. Values are: Wild clover and oat hay $7.50 per ton, alfalfa hay $7.50, bran $15, oil meal $27, corn meal $23.50, ground barley $22, rice meal $18.

If you will kindly suggest a better ration, would be much obliged, and will report results as soon as determined.

California. GEO. R. SNEATH.

The ration given above contains digestible nutrients as follows:

	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
30 lbs. alfalfa hay....	27.48	3.30	11.88	.36
5 lbs. bran.....	4.51	.63	1.93	.15
2 lbs. corn.....	1.78	.16	1.33	.09
1 lb. oil meal.....	.91	.29	.33	.07
Totals.....	34.58	4.38	15.47	.67

It seems almost incredible that any cow, not giving an extraordinary yield of milk, can utilize so much feed, and hence the presumption arises that an undue proportion of the nutrients pass off undigested. Cows, like men, can get into the bad habit of eating too much. Of course, these large cows must be expected to require more feed than small cows, and, if they are of the right temperament, they may also be expected to give a larger yield. For a herd averaging 1200 lbs. in weight, a daily allowance of 27 lbs. of dry matter, per animal, is believed to be quite ample. When the average weight is 1500 pounds, this allowance would reach about 33 lbs. This should suffice for cows in the ordinary full flow of milk, and may be decreased as the flow falls off.

Whether Mr. Sneath can safely make any material reductions in the amount of feed allowed to his cows is a somewhat different question. As we have said many times, cows are creatures of habit, and whatever seriously interferes with their accustomed routine is pretty sure to cause at least a temporary decline in the yield of milk. If he is feeding hay now three times a day, he might try reducing the mid-day allowance, little by little, and finally omit it altogether. The cow cannot get the full benefit of her feed unless it is remasticated, and feeding three times a day is not calculated to encourage this process.

Our California readers might get a hint for future guidance in raising crops for dairy cows, from the feeding experiments at the Kansas Agricultural Experiment Station, where kafir corn was used to supplement alfalfa hay.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

FEEDING STANDARDS FOR MILCH COWS.

Dry matter.	Digestible nutrients		
	Protein.	Carbohydrates.	Ether extract.
lbs.	lbs.	lbs.	lbs.
23 to 28	2.0 to 2.5	12 to 15.0	0.5 to 0.8

OAT ENSILAGE.

Please let me know the relative value of oat and corn ensilage; also the probable yield of each on good land.

We have 120 acres of tillable land in Angola. How many cows should that entirely feed and how much help would it take for both stock and cows?

In your opinion would it pay to raise heifer calves for cows when we can buy four or five year old grades giving 12 to 14 quarts a day, for from $35 to $45? All our milk is sold for six cents a quart, and skim milk at three cents a quart. T. M. D.

Buffalo, N. Y.

It is not advisable to attempt making silage from hollow-stemmed grain, for the reason that it is difficult to expel the air sufficiently to prevent decay. But even if it was practicable to put oats in silo, experience shows that in localities when the corn plant thrives there is no other crop that will yield as much forage per acre as corn.

The number of cows that can be kept on one hundred acres of tillable land depends so much upon the style of farming that one can make no approximate estimate of the number of cows that much land can be made to keep. Some farmers would easily keep 50 cows and the necessary stock to go with them, on that much land, while others would find it difficult to keep half that number. If much of he land is reserved for pasture the number of cows would not be as great as where soiling is largely practiced. In general farming it is estimated that there should be at least one good man for every 15 or 20 cows, and where milk is delivered to families, there is needed at least one man for each ten cows. We should prefer to raise cows rather than to purchase at the price named.

SILO DRAINAGE—COW STALLS—FLY REPELLENTS.

We are about to build a silo in the barn. It will be made of staves, about 12 feet in diameter; will dig a pit in the ground about five feet, and wall it up with stone for a foundation; build on that with 18 feet 2×4; will cement the bottom, filling in first, with small stones, about 6 inches. Would it be a good plan to leave a place in the center of the bottom uncemented, for drainage, or would you cement it all over?

What is the best and cheapest cow stanchion?

What is the best lotion to keep flies away from cattle? F.

Pine River, Wis.

It is not necessary to leave any provisions for drainage. They will only suffice to admit air to the silage and cause rotting of the same.

If the corn is in the proper condition when put in the silo, there will be no water or corn juice in the bottom of the silo.

We do not know of any cheapest and best stanchion, the two qualities do not go together. The cheapest stanchion is the old-fashioned kind, so widely used, but many dairymen object to the cows being kept with so little freedom of motion, and several stalls without this objection have been suggested. You will find ads. of several of them in the DAIRYMAN.

Several formulas have been given in the DAIRYMAN in the last few weeks, and you will find reliable preparations advertised in its columns.

NEW YORK FEED MERCHANTS.

A subscriber in the British West Indies desires the addresses of establishments in New York City, from whom he can purchase corn fodder, oat hay, wheat and rye straw, corn and rye bran, gluten meal, cotton seed meal and oil meal.

It will appear somewhat strange to home readers that we are inquired of concerning business establishments a thousand miles and more away, but it should not be forgotten that residents of other countries are likely to be as unfamiliar with distances here, as we are with the relative location of places there.

While, therefore, we cannot give the names of dealers in feed stuffs in New York, it will be quite safe to say that neither corn fodder nor oat hay will be on sale in any market, and that the price of straw will be much above its feeding value, because of the demand for it in paper making and for packing merchandise.

It is altogether probable that a letter addressed to, or an order placed with, any of the commission merchants in that city would receive prompt and careful attention.

SILO QUESTIONS.

I am desirous of building a silo for about twenty-five cows. Would like to know which is the most approved one to build outside, as I have no room in cow stable; also the name and address of some of the firms who build silos. F. D.

Lutherville, Md.

The kind of silo to build depends much on a man's taste; but the round, stave silo seems to have a preference in a majority of cases. For twenty-five cows you will need about 90 tons of ensilage. The silo should be 18×21, and will hold enough for 180 days feeding, but as the supply of pasturage is liable to be very uncertain, it is advisable to supply larger storage capacity, and store some silage for contingencies. The Williams Manufacturing Co., Kalamazoo, Mich., and Geo. D. Harder, Cobleskill, N. Y., manufacture stave silos.

A CITY RATION.

Having read your paper a couple of months, am impressed that we need a well balanced ration in the city, as well as on the farm.

Where we have to buy everything in open market, what is an economical and proper ration for Jersey cows, with feed at following prices?

Upland prairie hay $7 per ton, timothy $8; bran $12, shorts $14 and gluten at $14.

Des Moines, Iowa. H.

Upland prairie hay, if cut in proper time and well cured, is more valuable than timothy hay. On the contrary, if the prairie grass was well ripened before it was made into hay, it is decidely inferior to first-class timothy.

Assuming that in this instance the prairie hay is of good quality, we advise the following as a minimum daily allowance:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
15 lbs. prairie hay....	13.13	.52	6.27	.21
4 lbs. bran.....	3.52	.50	1.54	.12
4 lbs. gluten feed.....	3.69	.82	1.94	.20
Total.....	20.34	1.84	9.73	.53

Give a little salt every day, or better yet, with every feeding of grain—a small tablespoonful in all for the day.

The above is moderate feed for a small cow. If already on heavier feed, do not reduce the total amount, but apportion about as above. If now receiving less, increase the

daily allowance gradually as long as the cow responds at the pail and does not lay on superfluous flesh.

The amount of hay specified is simply an approximate estimate. The proper practice in all cases, where the animal is not a gormandizer, is to give all the hay or other roughage the cow will eat up clean. Never feed more than this.

WHO KNOWS ABOUT BROOM CORN MILLET?

Will you kindly advise me if broom corn millet is a desirable feed for cows, and will it make good silage? At what stage of growth should it be cut? B. P.

Havana, N. D.

"Broom corn millet" is a new term to us and one that we cannot find used in any of the standard works on forage crops or feeding. If any of our readers can answer the above inquiries we shall be much obliged.

RATION FOR COW ON GRASS.

Please give ration for cow on grass, with bran or meal costing $18 and gluten feed, $20. C.

Madison Co., N. Y.

It is quite impossible to give a formula for ration for cows at pasture, because one can never know with approximate certainty how much grass the cow gets, or what is its condition. Where good pasture is at its best, little or no grain is required. In fact, some good bright hay would be better than grain. When the pasture begins to get short and brown, there must be some soiling crop and grain to produce best results. About the best that can be done under the circumstances is to advise mixing bran and meal in equal proportions by weight, and feed enough of this to keep the cow up to a normal flow of milk. It may require only two pounds per day just now and four weeks hence six pounds may not be too much.

THE RELATION OF FAT TO VALUE OF SKIM MILK.

Does the amount of butter fat in milk show also the approximate comparative feeding value of the skimmed milk, or would you value all skimmed milk alike, as a recent correspondent did in estimating the comparative value of two cows?

Hamilton, N. Y. J. P. COLNON.

The solids-not-fat in milk vary somewhat as the fat varies, but not in equal amounts. Hence, the richer the milk in fat, the more valuable will be the skim milk; but as this increases in value, does not keep pace with the increase in fat, there is no way, except by tedious chemical analysis, for determining this increased value. Hence, it is customary to value all skim milk at a uniform price.

HOW MUCH MILK TO PAY FOR KEEP.

Alfalfa hay, two-thirds cured, is worth $8 delivered; bran at mill, $20.50; oil meal, $40; corn meal, $23; barley hay, $10. Have to buy all feed at present. What should an average grade Jersey-Holstein and Durham give per day to pay a profit at 40c per three gallon can? When should alfalfa hay be cut to be best for cows? O. W. L.

Los Angeles, Cal.

Thirty pounds of the two-thirds cured alfalfa hay and six pounds of corn meal would be a fair daily allowance per cow, and at the prices named would cost 19.5 cents. The income from a good cow ought to be about double the cost of her feed, in order to realize much profit. Cut for hay when in blossom.

WHAT TO FEED WITH GREEN ALFALFA.

Please give me a ration with the following feeds: Green alfalfa, green corn fodder, wheat straw, brewers' grains wet, barley, corn and cob meal, flax seed meal cake, wheat bran. If it is any trouble giving alfalfa in connection with brewers' grain, what is it? I have plenty of good green alfalfa the year round. J. R. T.

Morelia, Mexico,

We know of no special objection to feeding brewers' grains in connection with green alfalfa, unless it be on account of cost. Both feeds are in the nitrogenous class, and, hence, are not specially called for at the same time. With either one at hand, the other could be safely omitted, if necessary, or expedient.

When both alfalfa and the green fodder corn are used, the following allowance would constitute a satisfactory ration.

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
20 lbs. green alfalfa	5.64	.78	2.54	.10
20 lbs. green fodder corn	4.14	.20	2.32	.08
20 lbs. brewers grains wet	4.86	.78	1.86	.28
6 lbs. corn and cob meal	5.34	.38	3.78	.21
3 lbs. barley	2.67	.26	1.97	.05
Totals	22 65	2.38	12.47	.72

In addition to the above give the wheat straw *ad libitum*. The amount eaten will possibly approximate five pounds.

When there is no fodder corn, the alfalfa may be increased to take its place, and if the brewers' grains are omitted, increase the alfalfa correspondingly, and substitute bran for barley.

SUNFLOWER SEEDS AND SOJA BEANS.

Will you kindly tell me through your paper what is the composition and feeding value of sunflower seeds?

Are they suitable in a ration for a dairy cow?

How many can be raised per acre?

We sowed a small piece of soja beans this spring as an experiment, and I would like to know at what state in its growth it should be cut for hay?

I would not be without HOARD'S DAIRYMAN if I had to work nights for the price of it. WALTER R. R. C.

Gilbertsville, N. Y.

Sunflower seeds contain digestible nutrients as follows:

Protein	12.1 per cent.
Carbohydrates	20.8 " "
Ether extract (fat)	29.0 " "

Prof. Robertson, of Canada, some years ago proposed growing corn, horse beans and sunflower seeds to make a combination silage. The proportions were ten tons of green fodder corn, three tons of horse beans and one and one-half tons of sunflower heads. This mixture proved very satisfactory, both with milch cows and fattening steers. We are not aware of any experiments with the seeds alone, but should not hesitate to try them in a moderate way, commencing with, say, one-half pound or less per day, and gradually increasing the amount as results may indicate.

Soja beans, like all other plants intended for hay, should be cut sometime before ripening, or, say, when the greater part of the beans are fairly well formed, and earlier than this, rather than later.

PENNSYLVANIA FEEDING PROBLEMS.

I am on a small farm and trying to keep as large a dairy as the place will support. I use for fodder, corn hay, millet and barley straw. The grain produced on the place is barley, oats and corn. Now will you please give me a balanced grain ration for the best results in milk and butter regardless of whether it is produced on the place or not. Please give the ration for each of the above fodders. W. F.

Austinville, Pa.

It is not possible to make a satisfactory reply to this request without knowing what feeds are available and their approximate market value. The formula we submit below will serve to explain the difficulty.

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
25 lbs. corn stover	14.38	.43	8.10	.28
6 lbs. bran	5.29	.75	2.32	.18
2 lbs. oil meal	1.82	.59	.65	.14
2 lbs. cotton seed meal	1.84	.74	.34	.24
Totals	23.33	2.51	11.41	.84

If all these feeds could be had there is no question but what a ration following the above formula, would give good results, but it is quite possible that an equally good ration could be had for less expense.

We have specified corn stover above, but the letter as written reads corn hay. What is meant by corn hay?

We request W. F. to write again giving us a better opportunity to serve him acceptably.

PER CENT OF FAT IN MILK.

I have two grade Ayrshires which I have tested at the creamery. The first test was No. 1, 4.20; No. 2, 3.80. Second test was No. 1, 3.70; No. 2, 3.35. Third test was No. 1, 3.90; No. 2, 3.05.

I had these cows tested over three times, unbeknown to the man that tested the milk. The milk was handled the same each time, and if you have any idea why these cows differed so many points at each test, I wish you would please let me know. F. S. K.

North Ferrisburg, Vt.

Individual cows will frequently give milk differing in fat content from day to day.

On heavy feed, an attack of indigestion has been known to cause a difference of 2% in the fat content, while with cows on average feed, a difference of half a per cent, or even more, is not uncommon.

Such changes in fat content of the milk, as you observe, are not at all strange, and are as liable to increase as decrease.

OVERRUN OF BUTTER.

How many pounds of butter may I reckon to make out of 100 pounds of milk, testing by Babcock tester 4% butter fat?

I am thinking of starting a small creamery and wish for the above information to guide me in buying milk.

What return would milk of 3% butter fat give in 100 pounds?

Jamaica. H. FARQUHARSON KERR.

The average overrun for creamery work is about one-sixth. Thus 4% milk will make 4.66 pounds of butter. Of course the overrun will vary somewhat, above or below the average, according to the manner of handling the milk. Three per cent milk would give 3.5 pounds of butter.

CONDENSED MILK QUESTIONS.

Do condensed milk factories buy milk from cows fed on ensilage?

How much condensed milk will 100 pounds of 4% milk make?

Do condensed milk factories buy milk by the Babcock test?

What do they usually pay for 100 pounds?

What are they paying now?

How many pounds of cheese will 100 pounds of good 4% milk make?

Selma, Ohio. F. M. W.

The Michigan Milk Condensing Company buys ensilage milk and encourages its patrons to put up silos. We cannot say regarding other companies.

It will depend on what kind of milk is made, and whether a part of the fat is removed.

Analyses show that much of the milk in the market is partly skimmed, which of course will influence the yield.

The milk is bought by the hundred, but its quality is looked after very carefully.

The prices range from an average of 80 cents for summer, to $1.15 per hundred for winter milk.

One hundred pounds of 4% milk will make about 10.4 pounds of cheese.

WILD GARLIC FLAVOR.

Can you give me a remedy that will destroy the flavor of wild garlic in the milk and butter? R. F. S.

Appleton, Mo.

The following method has been successfully used by DeWitt Goodrich, of Iowa:

The milk is very carefully examined when received and all that is the least affected with the onion or weed flavor is set aside by itself and then run through the separator and its cream kept separate. To this cream is added twice its own bulk of hot water, in which saltpetre, in the proportion of one ounce to three gallons of water, has been dissolved. This raises the temperature of the mixed cream and water to about 160°, and it is immediately run through the separator again.

The result is, a fine, thick cream with no trace of weed flavor in it, and withal thoroughly pasteurized, and the Babcock test shows no loss of fat in the operation.

In practice, this cream is cooled and then mixed with that from the non-affected milk, the whole ripened naturally, and the resulting butter passes inspection by the most expert critics.

Of course, if all the cream were thus treated, it would be necessary to use some kind of a starter to re-introduce the proper species of flavoring bacteria, as those previously in the milk and cream were killed by the heat.

SORGHUM FOR FORAGE.

I would like some information concerning the value of cane or sorghum as a rough feed for cattle; also if there is danger in feeding a second or third growth of cane, either green or after it is cured. Some writers have contended that second growth cane frequently kills cattle. If this is true, is the harm done in feeding green or cured? Cane is raised largely as a forage crop in Nebraska, and while I have used it with excellent results, it has always been as fodder after being cured, and where there was a single crop raised in a season. I will be pleased to receive information on this subject from the editor or from some one of his corps of intelligent contributors. W. L. H.

Lincoln, Neb.

Prof. Henry in his work on "Feeds and Feeding," which ought to have a place in every farmer's home, says:

In the semi-arid region of the Southwest sorghum grows with great vigor, withstanding drought and drying winds remarkably well. Because of these characteristics and the abundant nutrient contained in stems, leaves and seed heads, the sorghum plant is destined to occupy a prominent place in the agriculture of this district, furnishing green forage to stock during shortage of pastures in summer and fall, and the best of dry fodder in winter.

He also quotes from various station reports showing that second growth sorghum is credited under certain unknown conditions with being very destructive to cattle. In a Mississippi bulletin it is said: "It seems to affect only certain animals, or perhaps only certain plants produce the ill effects, as generally only a few animals in a herd are killed, and these are commonly found near together."

The reports from individual farmers which come to HOARD'S DAIRYMAN are exasperatingly conflicting. Some of our readers write that they have used second growth sorghum for years without experiencing any trouble whatever and consider it one of the most profitable forage crops that can be raised, whether for soiling purposes or for winter feeding. Others report cases where the green sorghum has undoubtedly proven fatal. We do not now recall a case where the dry fodder has proven injurious, but shall be very glad to hear further from our readers on this subject.

COW PEAS FOR FERTILIZER IN WISCONSIN.

Is it advisable to sow cow peas for fertilizer on oats ground after the oats have been harvested? Which is considered the best way of putting in the seed? When is it most profitable to turn them under, spring or fall? R. K.

Waukesha, Wis.

There has not been sufficient experience with the cow pea in northern latitudes to warrant a specific answer to the above inquiry. We certainly could not recommend more than a trial in a small way.

The few experiments made last year and the year before with crimson clover, seem to indicate that it is well adapted for the purposes above indicated. The senior editor tried them in a limited way, last season, and was much pleased with the result. He turned the crop under in the fall, but some of the experts say this is not the better plan. There is a growing conviction that it is not desirable to expose a bare surface to the elements, even in winter, but this is contrary to the practice of many first-class farmers. Until more definite experiments are reported, we should be largely governed by the matter of convenience in getting the season's work advanced. If fall plowing would sensibly expedite the spring's work, we would plow in the fall.

Comment and Suggestion.

Speltz Wheat, and the Moral it Teaches—Planting Corn the Last Week in June—Cost of Production as Important as Amount of Production—Spare, Deep-Bodied Cows are Economical Producers.

ED. HOARD'S DAIRYMAN:—Referring to the note from A. P. McKinstry, in regard to speltz wheat, will say that the sample reached the experiment station and analysis of same shows that it contains an unusual amount of protein which is a pretty fair measure of its feeding value for dairy cows. In the following table is given the percentage of protein in our ordinary grains:

Speltz	14.6
Barley	12.4
Wheat	11.9
Oats	11.8
Sweet Corn	11.6
Field Corn	10.4

The high feeding quality of the speltz is quite in harmony with some other peculiarities noticed in grain intended for feed. I have noticed that slim or small kerneled barley contains a larger per cent. of protein than is found in the full, plump berry; that shrunken wheat or barley makes better feed for cows than when the kernels are well filled and rounded. The average per cent of protein in wheat is 11.9, while the average for our high grade hard wheat is 13.75. The wheat grown in the Red River Valley has not a plump, berry but is small and thin, resembling the wheat we used to find in the screenings years ago when I was a boy. Isn't it strange that we all admire a fine, well rounded berry and assume that that kind is the best, just as most people do about a cow. They blindly prefer any big hulk, never stopping to consider as to whether the big thing is adapted for the work she is to do. We all are more or less afflicted with the "bigs." If anything is large and looks well then it is satisfactory.

This is the 23d of June and we still have a field of ten acres to seed to fodder corn. The ground is ready and the corn will be planted before the close of the week. We intended to get it in by the 20th, but the field was low and frequent rains kept the soil so wet that we could not work it.

Last week we turned over ten acres of timothy, on which the cows had been grazing, and planted it to fodder corn. The ten acres would have yielded about twenty-five thousand pounds of dry matter, while the ten acres planted to fodder corn will yield from seventy-five to eighty-five thousand pounds. We planted in double drills and the double drills forty inches apart; kernels from one to two inches apart in the row.

I notice in your last issue that Prof. Soule says in a paper read before Rural Science Club of the University of Tennessee, that "if you find a cow that gives 5,000 pounds of milk and yields 300 pounds of butter you have a cow well adapted for that speciality"—butter producing. Had he added "at a reasonable cost" I would be better pleased with the statement. Too many are losing sight of the present office of the dairy cow. She used to be a mere convenience to the household, and so long as she gave a fair mess of milk she was to all intents and purposes a good cow. It did not matter whether she could yield two or four hundred pounds of butter, or whether she charged five or ten cents, so long as she gave milk for the babies, cream for the coffee and now and then a roll of butter. Not so now. She has stepped into the commercial arena and her product now comes in competition with that of other countries and if she fails to produce it as economically as they do, she will be discarded just as surely as was the hand sickle, the cradle, the reaper, and the harvester. The time was when the price of butter was such that a dairyman could make money with any kind of a cow; but when butter is fifteen cents a pound he will have to look very close to the expense account, or his profits will not meet the requirements of the times.

Take bran at $12, linseed meal at $25, hay at $6, oats at 30 cents, corn at 28 cents, and barley at 35 cents and see what a close margin there will be between the cost of production and the receipts for the products. And then when you take into account the many steps required to produce a fine article of butter and the many leaks and losses, one comes to the conclusion that he gets little enough pay for the most economical producer. So the question of cost comes foremost. What benefit is it to me if my cow gives 300 pounds but don't give it at a profit? Cows of that caliber cost, for keep, from $30 to $35 per year. So if the product nets 15 cents we have from $10 to $15 per cow, which would require an enormous herd to bring a profitable income.

It may be a very difficult matter to judge from a picture the amount of milk or butter a cow will yield; in fact, is a difficult matter to tell it from a close inspection of the cow. Really, it is a matter in which the dairyman is not very greatly concerned. The question that interests him is the usefulness of a cow, not in any one year, but during her lifetime. How much can she earn? And fortunately this is a much easier question to decide than the quantity of milk or butter yield for a given year. One may safely take a cow of the spare, deep-bodied type into the dairy for there will not be one disappointment out of twenty, and then if one is found that brings disappointment, an examination into her history will show that the owner was at fault.

I find that the daily food of maintenance is about twelve pounds of dry matter per thousand pounds of live weight for an animal having a quiet, tractable disposition, and that with others it may require as high as fourteen pounds; that it requires from eight to nine pounds of dry matter, over and above that needed for food of bodily maintenance, to provide the nutrients required for the milk that will yield a pound of butter fat; that cows in calf will store up during the latter part of their period of gestation reserve energy and nutriment and that after parturition, at least a portion of the reserve is available either for the production of milk solids or for bodily maintenance. If a cow has a strong dairy heredity she will, during the early part of her period of lactation, milk down the surplus weight and may thus be able to produce considerable more butter than the nutrients in the food she eats during that time can provide for. But this excess in yield will gradually decrease as she approaches her normal weight, after which she can yield only as much butter as the nutrients consumed in the feed, in excess of that needed for bodily maintenance, provide for. She may, however, when the lacteal functions are exceptionally active for a time, continue such excess yield by drawing on body tissue and fall below her normal weight. But the time comes, sooner or later, when she must make good this loss and she can do it only with the nutrients provided over and above the amount needed for support and must then rapidly decrease in butter yield. Again, a cow having considerable rest during the latter part of her period of lactation may store up a large reserve and not having a strong dairy heredity fail to milk down the increased weight, in which case she would require proportionally more food for bodily maintenance, and would have proportionally less available for dairy products. Cows also vary from year to year in physical tone and appetite. Some years they are in high feather, physically, and will do an abnormal amount of work, but in such instances they will generally do an exceptionally small amount of work the year following. It therefore follows that a cow's usefulness in the dairy cannot be determined from a single year's work, neither can it be determined in a number of years, unless an exact account is kept of the amount and cost of the food consumed.

It is simply a question as to how much food she can eat and digest, over and above that needed for her own support, and what disposition she makes of the surplus. It is, therefore, important that she is provided with a capacious and active middle which will enable her to eat and digest much, that she has a dairy heredity, and has light quarters in order to reduce the food of maintenance to the minimum. Our records show that it takes as much food to put a hundred pounds of solid gain on a cow as it does to produce a hundred pounds of butter and that every hundred pounds of surplus tissue on a cow reduces her butter capacity by about one pound in eight days or about 37 pounds per year; and in view of the fact that an increase in weight does not increase her feeding powers, it is a matter of considerable importance whether she weighs 900 or 1,200 pounds.

So let us get down to the business end of the question and study the cow from the standpoint of a money maker. The question is not how much butter or milk she yields, but what will she earn for us.

T. L. HAECKER.

Seasonable Notes From Michigan.

Packing Dairy Butter.—Handling the Cream.—Selling Packed Butter.—Demand for Summer Make—Summer Pasture.

ED. HOARD'S DAIRYMAN:—"I am going to begin to pack my butter next week," said a farmer's wife the other day. "We always stop selling the first or middle of June, when the price gets very low, and put the summer's make into crocks and keep it until fall."

Knowing that the lady had a good reputation as a butter maker, some questions were asked concerning her method, resulting, substantially, as follows:

"About ten cows are kept, and the milk creamed by the deep setting process, allowing it to stand twenty-four hours before drawing off.

The cream is kept in tin pails or cans under the water vat of the creamery, where it is cold enough to prevent its getting over sour between churnings, which occur every other day.

Great stress is laid upon having the cream not over ripe, but just nicely acid when churned. Butter from such cream keeps longer in good condition, than that made from cream excessively sour. Another point is to churn the cream quite cool, so that the butter comes hard. It is gathered in granules, thoroughly washed from buttermilk, and salted rather heavy. It is worked twice, the second time very lightly, however, then packed in stone crocks and covered to the depth of an inch or more with very strong brine, a saturated solution, in fact. This brine is renewed every little while during the summer, as evaporation takes place, the object being to thoroughly exclude the air from the butter. Between the butter and the brine is placed a circle of parchment paper.

The coolest corner of the cellar is chosen for the crocks, and the door and windows are kept closed during the middle of the day, when hot air would enter.

In the course of the season the family use from the butter first made; in this way all the June make is disposed of. In autumn, when the price rises, the butter is sold.

Sometimes buyers refuse the packed butter, and then it is that it is taken from the crocks and made into rolls, a process involving considerable labor, but paying one, however.

Several hundred pounds are put on the market at once in this way, and a nice little sum realized, with the satisfaction of knowing that it is bringing several cents a pound more, than if sold during the summer.

The writer does not recommend keeping butter in this way for the average farmer. One needs to have better facilities for storing, than are ordinarily found, to do it satisfactorily, and the disappointment, if it should prove a loss, would be great. It is much better, as a rule, to sell as fast as made.

Let pains be taken to find steady customers, asking about what would be realized in the fall. I know of farmers' wives who do this; disposing of all they make through the summer, at from 15 to 18 cents a pound.

The most common fault with summer butter is, that it tastes sour or over ripe. Such butter is, no doubt, made from over ripe cream. To add to this tendency to sourness in taste, is lack of thoroughness in washing. All the buttermilk not being removed, it soon turns rancid; for what smells so vilely as buttermilk, allowed to stand several days in warm weather, when decomposition progresses so rapidly.

Thorough washing is a necessity, if butter is to be kept any length of time in hot weather. If to carelessness in washing is added too high a temperature, so that the butter globules become broken, the matter is all the worse.

A dairyman in an adjoining township who owns a large herd of Jerseys keeps all his summer's make of butter until about October. He has excellent cold storage facilities; a refrigerator built after the plan of those in markets, roomy enough to accommodate thousands of pounds.

The churnings are done regularly, from carefully ripened cream, butter washed and salted in granular form and not worked sufficiently to break the grain It is then packed into one gallon stone crocks, leaving an inch of space at the top of each. A circle of butter cloth covers the surface and this is filled in with salt snugly packed down. The jars are set on shelves in the storage room and no further attention paid them until fall. Of course the supply of ice is not allowed to get low. I asked why butter cloth was used over the butter instead of parchment paper, and was told that the latter often shows greenish spots after it has stood several weeks, the supposition being that the action of the salt upon it caused it to become discolored by reason of the chemicals used in bleaching. For this reason it was discarded and cloth used instead.

There is not the demand for June made butter that formerly existed. We rarely find parties now-a-days who prefer it for winter's use as was frequently the case a few years since. The reason for this is found in the fact that at that time few farmers manufactured butter during the winter months and it was more difficult to secure that which was freshly made, in which case well preserved June butter was in demand.

It is an indisputable fact that the so-called creamery butter, whether made on the farm or at the factory, does not possess the keeping qualities of that made by the open pan system.

I think the reason for this is not difficult to find. In the old way a medium temperature was preserved throughout the process. The milk and cream were exposed to the air and no attempt made to reduce the temperature of either milk or cream below the normal. Butter thus made is, it seems to me, better prepared to stand a temperature such as is ordinarily found in a farm house cellar during several weeks of warm weather, than that where an abnormally low temperature is maintained until after the butter is made, then allowing it to take its chances in an ordinary cellar.

By far the better way, in my estimation, is to sell as fast as made, securing even a few cents over the regular market price by de-

"He Laughs Best Who Laughs Last."

A hearty laugh indicates a degree of good health obtainable through pure blood. As but one person in ten has pure blood, the other nine should purify the blood with Hood's Sarsaparilla. Then they can laugh first, last and all the time, for

Hood's Sarsaparilla
Never Disappoints

Not a Preservative

but a preventive. If you would have your milk keep sweet longer and be free from all objectionable odors, use a CHAMPION Milk Cooler-Aerator. It does its work perfectly and it's use does'nt violate any law—it doesn't need to be used on the sly. Our book "Milk" is free.

CHAMPION MILK COOLER CO.,

livering weekly or semi-monthly to private customers.

It is hard work to make butter, especially where conveniences are lacking; yet one who is determined, will secure desired results even if she has to hang her cream and butter in the well in lieu of cooling it with ice.

Not long since I visited a dairyman who had had the misfortune to break his milk separator and for a time was creaming his milk in large cans. These had tubes running through them to allow circulation of water, the cans being placed in tubs of cold water, skimming being done twenty-four hours after setting.

The fear was expressed that considerable butter fat was being lost, so the Babcock machine was brought into use and a test of the skim milk made. A most gratifying showing resulted, it was found that the amount of fat remaining was so small as to be perfectly satisfactory, in fact scarcely any was perceptible, a surprise to all who witnessed it.

Nice rains have visited this section of the state, but pastures had become quite short before they came. This method of feeding is most costly of all. The amount of forage grown upon one acre of good land will furnish ten times the food material obtained by pasturing, as has been proven to my entire satisfaction. Where one has waste land, that which is untillable, pasturing is of course the only way of utilizing it, but it is very wasteful to turn a herd of cattle into a field of good clover, much more being trampled under foot and wasted than is consumed.

The ideal way of keeping cows, in my estimation, is to keep them in darkened stables during the heat of the day, turning them out in some convenient paddock or yard at night; furnishing them abundance of food by way of soiling crops, beginning with early cut rye and finishing with corn. It is astonishing how far one acre of clover, for instance, will go by feeding in this way.

Mich. W. C. ROCKWOOD.

Observations on Tuberculosis in the Storrs (Conn.) College Herd.

Tuberculosis and Dairy Capacity.

ED. HOARD'S DAIRYMAN:—The Storrs College herd has recently been tested with tuberculin, and eleven animals out of twenty-five responded to the test. There is a prevailing opinion that the most productive dairy cows, on account of the greater tax upon their systems, are less hardy, and more susceptible to tuberculosis than those only moderately productive. This opinion is not substantiated by our experience, as the following observations show. If these twenty-five cows are arranged in the order of their butter production, with the one having the highest yield first, then those designated by the following numbers reacted: Numbers 1, 2, 4, 11, 13, 15, 18, 21, 22 and 25. Fifty per cent fall in the half of the herd having the lowest records. In the same line, it is interesting to note that one Jersey out of four, one Guernsey out of three, one Ayrshire out of four, and eight grades out of eleven responded to the test. And according to type, two 'Typical Dairy', four 'Dairy'; three 'Lacking Digestive Capacity', and two 'Beef Type' responded.

THEORY OF INFECTION.

Great care has been taken to avoid the introduction of tuberculosis into the herd. The tuberculin test has been used frequently, (once a year). All animals purchased have been tested before, or shortly after coming into the herd. Up to the fall of 1898, we have had no animals respond, and no known case of tuberculosis. A year ago last November, there was purchased an eight-year-old cow (No. 18) of a neighboring farmer. This man raised the cow from a calf, and reports that he has never had a case of tuberculosis in his herd, and that he had never used the tuberculin test. Cow No. 18 was tested with tuberculin soon after purchased, and not responding, and showing no physical signs of disease, was given a permanent place in the herd. A year later, she commenced to refuse her feed, ran down rapidly, and died after one month's sickness. An autopsy showed a generalized and advanced case of tuberculosis. The herd was immediately tested with tuberculin, when eight cows responded, and again after five months, when three more responded, or a total of eleven out of the twenty-five cows in the herd. The most plausible theory of infection, to us, is that cow No. 18 was, when purchased and tested with tuberculin, suffering with the disease in an advanced form, and for this reason did not respond to the tuberculin test. It is hardly reasonable to believe that in less than one year, she could have contracted the disease, and that it should have developed to the extent that the autopsy showed. Dr. N. S. Mayo, our college veterinarian, reports:—'Judging from the extent of the disease, and the number of encysted tubercles, I am of the opinion that the case was one of long standing.'

PROPOSED OBSERVATION.

Two courses are open to us in the management of the herd. First, to kill the infected animals; or, second, to isolate those which responded to the tuberculin test, and keep them under the best sanitary conditions until they show some physical signs of breaking down. In order to form some idea as to the condition of the reacting animals, five of the eleven that responded were killed. The animals selected for slaughter were the ones that showed, most markedly, physical signs of disease. Four of the five had twice responded to the tuberculin test. The autopsy showed that the disease was, in each case, in the earlier stages of development. The mediastinal gland in each animal was affected, and in addition, the bronchial gland in one case, and in two cases one lung each—in one animal slightly, and in the other quite seriously. The animals slaughtered showing so little affection, it was then determined to isolate the balance of the reacting animals, and keep them under observation.

At present, the reacting herd is quarantined in a barn adjacent to the one occupied by the healthy herd. This barn is well ventilated, and admits plenty of sunlight. The infected herd occupy a separate yard, pasture, and watering place from the healthy herd, and at no point do the two herds come in contact. As little communication as possible is permitted between the barns. The attendant who milks, feeds, and cares for these animals, waits first upon the healthy herd, and later upon the infected herd, and only in this order. A special over-suit and shoes are provided to be worn by the attendant while at work in the stables occupied by the infected herd.

More stringent rules in regard to communication, even to complete isolation, could be made and enforced, but if this experiment is to be an object lesson of practical value, the conditions must be such as could be applied upon any farm. C. L. BEACH.

Storrs, Conn.

Assimilation of Nitrogen by Legumes.

In the report of the chemist of the central experimental farm Department of Agriculture, Canada, we find the following note on this important subject, as yet but little understood by farmers generally. "So many letters," Mr. Frank T. Schutt, the chemist, writes, "have been received during the past year respecting this question that it may prove of more than passing interest if I here insert brief replies to some of the more frequently occurring and important inquiries:"

1. Do the legumes absorb nitrogen by the leaves?

A.—There is no nitrogen assimilated by the leaves of the legumes. All absorption of free nitrogen is by means of the bacteria in the nodules on the roots.

2. Do the legumes use nitrogen other than that in the air?

A.—Legumes, like all other plants, can make use of soil nitrogen (not free nitrogen), and this they specially do when young. Unless the soil is somewhat poor in nitrogen—when it is said to be "nitrogen hungry"—there appears to be but little assimilation of free nitrogen and but a poor development of nodules.

3. How can it be said that the free nitrogen of the atmosphere is utilized by the legumes, when it is stated that assimilation is by roots?

A.—The free nitrogen made use of by the micro-organisms in the nodules is in the air occupying the interstices of the soil. In all soils, but especially in well drained and light soils, there is a large quantity of air.

4. How do the organisms in the nodules make use of the nitrogen, and what becomes of the nitrogenous compounds formed in the roots?

A.—It is not known how the legumes utilize free nitrogen and convert in into organic compounds. It is, however, evidently a life function.

The nitrogen compounds elaborated in the nodules migrate (most probably as amides, soluble compounds afterwards converted into albuminoids) into the stems and leaves. This, as a rule, leaves the roots poorer in nitrogen than the foliage. The ratio of the nitrogen in the roots to that in the foliage is a fluctuating one, depending chiefly on the stage of growth or maturity of the plant.

5. When is the best time to turn under a crop of clover or other of the legumes?

A—After the time the seed has begun to form, there will not be much more assimilation of free nitrogen. If, therefore, it is wished to enrich the soil, in addition to the nitrogen, with a large quantity of humus capable of ready decomposition in the soil, the plowing should be done soon after the flowering of the plant, and before the fibre becomes hard and the nitrogen for the most part gone into the seed.

If sown after cereals as a "catch" crop, it will usually be the best practice to plow it under in the autumn, at the end of the growing season. If sown as a "cover" crop, as in orchards, it should be left till the following spring.

6—What loss of nitrogen would ensue on allowing the clover to freeze down and remain uncovered all winter?

A—There would, in all probability, be some loss, but unless the winter were an open one, it would be very slight.

7—Is green manuring with the legumes as profitable as purchasing commercial fertilizers?

A—Under ordinary circumstances it is the cheapest and most economical means of supplying nitrogen and humus---both essential constituents to soil fertility. Green manuring not only enriches the soil composition in these elements, but adds largely to the store of available mineral food, and greatly improves the tilth of heavy clays, light and sandy soils, and all soils deficient in humus.

Dairy Business.

It is noticeable that in every community, in which the dairy is well developed, there is a high degree of prosperity and refinement. The influence of the business is uplifting. It requires intelligence and a wide study to make the business a success, and all this is on the line of refinement. It demands gentleness of disposition. No rough, brutal man can achieve success in the dairy. He must be kind, and, if not naturally so, he must cultivate the spirit of kindness. The cow must be loved, must be petted, must be fed well and fed properly, and all this leads to the broadening of the mind and the improvement of our natures. Then, there must be cleanliness, not only about the premises, but about the person. An Indiana dairyman has a covered barnyard, and he was asked at an institute if he was satisfied with that way of keeping manure. "Why," said he, "I do not have a covered barnyard for the purpose of keeping manure. All manure is hauled out as soon as made in order to keep the yard clean. I constructed a cover over the yard for the comfort of my cows." There was a whole volume of dairy instruction in those few words. The watchfulness to preserve cleanliness and the kindness to the cows are the corner-stones to successful dairying.—*Practical Dairyman.*

Only Thirty and Gray

How is this?

Perhaps sleepless nights caused it, or grief, or sickness, or perhaps it was care.

No matter what the cause, you cannot wish to look old at thirty.

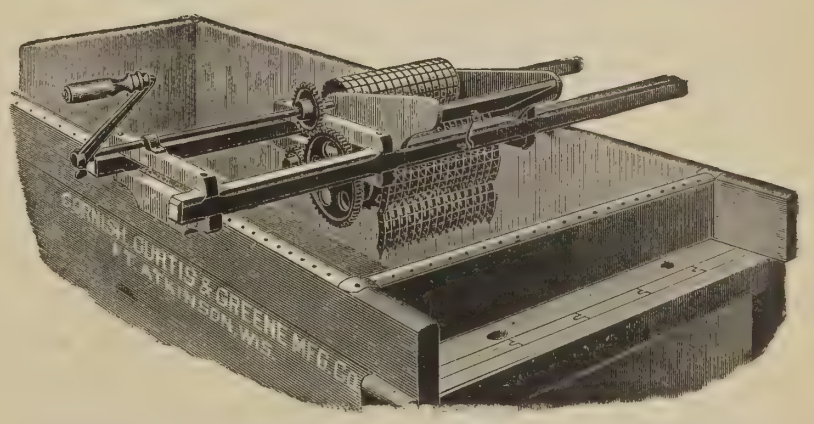
Gray hair is starved hair.

The hair bulbs have been deprived of proper food or proper nerve force.

Ayer's Hair Vigor

increases the circulation in the scalp, gives more power to the nerves, supplies missing elements to the hair bulbs.

Used according to directions, gray hair begins to show color in a few days. Soon it has all the softness and richness of youth and the color of early life returns.



Would you like our book on the Hair? We will gladly send it to you.

Write us!

If you do not obtain all the benefits you expected from the Vigor, write the doctor about it. He may be able to suggest something of value to you. Address, Dr. J. C. Ayer Co., Lowell, Mass.

Kasper Rotary Curd Mill.

The demand for a large capacity curd mill for cutting curd into cubes has induced the inventor to bring out the Kasper Mill. In construction the mill consists of a rotary cylinder made of knives in the form of cubes. Against these knives a wooden roll revolves with indentation to fit the knives of the cylinder; the curd being fed into the hopper is forced through the openings in the cylinder by the wooden roll. The cylinder is made in three sections hung on hinges, and, as it revolves, each section as it comes to the lower part of the cylinder, opens and allows the curd to drop into the vat, the section closing again as the cylinder revolves.

It is estimated that the curd from 7,000 lbs. of milk can be cut in from 7 to 10 minutes. The mill operates easily, being light running and adjustable to either hand or belt power. Simplicity of construction, durability and ease of cleaning are some of its principal features. All parts being galvanized or tinned prevents rusting. Weight of the machine complete is about 38 pounds. List price, **$25.00**

Nuisances in the City Milk Supply.

(Continued from May 5th.)

ED. HOARD'S DAIRYMAN:—While the readers of HOARD'S DAIRYMAN may think they have had enough of these nuisances, still I am sure if they will keep up their patience and read these final remarks, they will admit that at least some of these should not pass unmentioned. While it is a well known fact that the process of bottling the milk and cream, shipped by railroads to the city dealers, is by no means done in such a careful and cleanly manner as it should be, still only a very few consumers have the remotest idea of some of the nasty, not to call them still worse, ways in which this is done.

Even in the very best and cleanest city dairies we find it common practice that the men or boys who put up the milk, carry the empty bottles to the filling table by sticking one finger (clean?) into each bottle, thus carrying ten bottles at a time.

The bottles have often been standing all day in a warm room, full of dust and flies, with the open end up, and I recollect cases of caterpillars being found in the milk, having lowered themselves down into the bottles from the ceiling during the day.

We use racks with wire bottoms and partitions in which the bottles are placed during sterilization, and in which they are left till just before using; never set a bottle flat with the bottom up on a filling table, as no matter how clean the table, if the air has no access the bottles will soon smell foul, which applies just the same to the large milk cans and other vessels.

The caps used for the "common sense" bottles are carelessly handled, left in some vessel near the bottles being filled, and some splashes of milk often reaches them. Some are then left for next day's use, nobody paying any attention to the mischief which may be done to the fresh milk or cream by a drop of old milk on a bottle cap.

Then the milk which overflows the bottles in filling and runs over the table is caught in pails below and poured right back into the general supply. Now, if (and that is an important if) the table was kept strictly clean and free from dust, this might not be so bad, but how often have we not seen some of the boys, the same who drive the milk wagons and tend to the horses, leaning upon the table with clothes on, which were not as clean as they look in some of the advertising pamphlets, yes, even sitting down on it. And yet, we all learn, or at least may do so continually.

I learned one trick which caps the climax, in my experience, as to nuisances in the city dairy; I can vouch for the truth of this, and could give the name of the well known dairy, which runs several retail wagons here in Washington. A colored man, who was bottling milk,

HELD THE PAPER CAPS BETWEEN HIS TEETH

in the same manner a plasterer holds the tacks with which he is going to nail on the slats for plastering. I shall make no comment on this extraordinary clever proceeding, but will only ask the producers of good, clean milk if they do not think it a good idea, that they should find out for themselves how their milk is handled by those who retail it?

The producer may think it none of his concern what is done with his milk in the city, just so that he gets his pay. But mark it, some day he will find to his sorrow that it makes a difference, just as much as it does for a butter maker to have his product properly taken care of by the dealer. And while the holding of paper caps between the teeth is rather bad, still I believe it almost as bad when a milk driver keeps a collection of caps in his vest pocket, together with dirty coins, old tobacco, etc., etc., and while on the wagon fills a bottle taken from some house, and puts on a cap from his vest pocket. And this you probably know is a common practice in all cities, that may be observed daily in the streets. The wonder is that no health inspectors interfere. This makes me think of the rather useless manner in which

SAMPLES ARE TAKEN FOR INSPECTION.

Here is the way: The other day a gentleman entered our office at the laboratory, handed me a small medicine bottle (sterilized) and asked me to put in a half pint of milk, such as we sold. I, of course, knew at once that he came from the health officer, and I did not hesitate to tell him, that it certainly would be a very easy matter for any dairyman to give him of his best milk for a sample, and that he certainly would not give him any of the inferior kind he sold to some.

The fact is that the whole manner of milk inspection is perfectly ridiculous. And yet, while we thus may be sure that no inspector gets the *worst* milk kept for sale, still many samples show very inferior quality; what would the result be if the samples were fairly taken from the average supply? And I see no chance for any real improvement in the milk supply of our cities, until sufficient means are provided by the city authorities for an efficient inspection by men who understand all about milk and its proper treatment.

NEW AUTOMATIC MILK DISTRIBUTOR.

It is claimed from Germany that after much tedious experimenting, one, L. Hoffman, has finally succeeded in putting upon the market a practical apparatus for the above purpose.

The "Milk Automat" is so arranged that it not only will supply milk and receive payment for same, but also keeps the milk in proper condition by stirring and cooling, and cleans the drinking cups. When "sold out" it shows on the outside, and at the same time the receivers for cash will be closed.

This apparatus should be of considerable value to milk dealers, as it would make distribution of milk easy in schools, play grounds and public places of amusements. If the apparatus really is what is claimed for it, we shall be sure to hear more of it; it looks as if it might be of considerable value in this country, where all distribution and delivery is far more expensive than in Europe.

Washington, D. C. J. MOLDENHAWER.

Function of Fertilizer Ingredients.

ED. HOARD'S DAIRYMAN:—There is no question on the farm of greater importance, and probably none is less understood, than that of the functions of the fertilizer ingredients. When we speak of fertilizer ingredients, we mean nitrogen, potash, and phosphoric acid, and it may be well to add lime, since this material also is a factor in farming. It is generally admitted, and as a rule well understood, that the object in fertilizing a soil is to supply nitrogen, potash, and phosphoric acid, hence a complete fertilizer may be defined as one that contains these three ingredients. Each has its own part to play, and one cannot take the place of another. All three must be present, and in the proper proportions in order to insure full returns.

Nitrogen has much to do with promoting the growth of leaves and stems. Besides it has a very marked effect upon the foliage, deepening the color considerably. Nitrogen can be supplied in several ways; first, employing mineral substances, like nitrate of soda and sulphate of ammonia. Secondly, by the use of organic material, such as tankage, fish scrap, dried blood and cotton seed meal. If too much nitrogen is applied, it tends to a too rapid growth of foliage at the expense of fruits or grain, as the case may be. The effect of a disproportionately heavy application of nitrogen is well illustrated by stable manure, which is a natural fertilizer, containing considerable nitrogen. Every farmer knows, that when he puts on a heavy dose of barnyard manure, a luxuriant growth of foliage results. The cheapest and best way of supplying nitrogen is by growing clover, cow peas, or other plants of the leguminous family, which have the faculty of absorbing this ingredient from the atmosphere.

Phosphoric acid seems to hasten the maturity of plants; it also causes the crop to assimilate other ingredients to better advantage, and unless there be plenty of phosphoric acid available for the plant, it will not come to maturity, and therefore produce no seeds. Phosphoric acid can be supplied in the form either of acid phosphate or of dissolved bone, both of which are cheap and readily available sources.

In the growth of plants, the formation of starch is a prime consideration, and potash is necessary to assist in this process. It also causes a development of the fleshy portions of fruit and of the woody parts of the stems of plants. Its action is distinct, and can not be performed by any other element of plant food. The main sources of potash on the market are muriate of potash, sulphate of potash, kainit and double manure salt. Woodashes also contain a small quantity of potash.

Although the function of lime is dwelt upon here, this ingredient is not included in the same class as the other three just enumerated. There is usually, if not always, a sufficient supply of lime in the soil from which the plant itself can feed. The principal value of the lime, however, consists in its action upon the soil. It improves the physical condition of heavy clay soils by loosening them and when supplied to light sandy soils, it has a tendency to bind the particles together, thus making such soils more compact. When considerable animal or vegetable matter is present in the soil, a dose of lime will hasten its decomposition, and convert the same into available food for the plant. The best form to apply is the slacked lime, which should be used at the rate of 25 to 40 bushels per acre. The proper time for the application of this material is the fall or winter, or at any rate early in the spring, some weeks before planting time. When put on this early, it is afforded plenty of opportunity to sink into the soil and to accomplish its important mission.

GEO. WILSON.

Segworth Farm Notes.

Boulders.—Jerseys.—Short-horns.

ED. HOARD'S DAIRYMAN:—If we were to take the opinion of the farmers all over our country, in regard to their preferences for cows, some would choose one and some another breed. Having been raised on a farm, and always to a certain extent been a dairyman, after going for myself I worked in the oil country for a few years, but my heart yearned for a farmer's life, so eighteen years ago I moved on my present farm, which consisted of 100 acres.

It was very poor, worn out by excessive grain raising; stone piles in every field; fence rows grown up in brush and not a rod of good fence on it, with buildings in a chronic state of dilapidation, and all my capital invested; no machinery, a worn out but strong team, and lots of days' work, and hopes of success in myself.

I had always been on a smooth farm and could not farm around boulders and stone piles, but by the use of dynamite and lots of elbow grease, and after a good many back aches, my boys and I can sit down and look across our fields and have the satisfaction of knowing that all of the obstructions large enough to harm a binder, are in one corner, and not more than a dozen of them, and, Mr. Editor, although several of them will weigh 50 tons, they too will go next year.

On the 60 acres that we farm, we have blasted out 200 boulders, and hauled off with a chain at least 1,000. Now this is not a fish story, either.

But I started to tell why I choose the Jerseys. I was located six miles from Franklin, a city, then, of 5,000 inhabitants; now it contains 10,000. I concluded to keep some cows, and bought three head of natives, part Short-horn and part just plain cows. I bred to a neighbor's grade Short-horn bulls, which were chosen specially from a milk strain of dams, and got a herd of, for that time and place, good cows. In a few years I began breeding to a grade Jersey, and two years ago I purchased a pure blood Jersey of the Stoke Pogis family. I have changed bulls several times since, always getting a pure blood.

A few years ago a neighbor imported a herd of Holsteins, and it was said that they were the ideal farmer's cow for beef and butter, so I went to see for myself. We both used the Cooley system of cream raising; he had a cabinet, I had a good spring of water. I did my own work, he had a foreman and bossed the job.

I got on an average 1¼ gallons milk, per cow, per milking, which showed on our cans 10 to 13 spaces of cream per can, of 4½ gallons; he got 2½ gallons of milk, which made 8 to 10 spaces of cream. I churned from 1½ to 1¾ pounds butter per gallon of cream; he churned from ¾ to 1¼.

Now I was feeding a 600-lb cow to get better results than his 1200-lb., and concluded I had better stick to my pot-bellied Jerseys. This beef idea is a delusion any way; 25-cent butter and 3-cent beef won't average. Our herd at the present time contains 3 two-year-old heifers and a number of old milkers, and after using lots of cream for berries (we grow our own berries and use some days 10 quarts) ice-cream, etc., we average 1¼ pounds, per cow, per day.

Swift said, he who caused two blades of grass to grow where one grew before was a public benefactor. If he told the truth, I am trebly so, for I have caused at least four to grow where none grew before, and I say all thanks to the Jerseys. SIGWORTH FARM.

Western Dressed Beef, Sheep, Veal, Hog Products, Etc.
OAKDALE AVE. & HERNDON STREET.

THE EDGEWOOD REFINING CO., CHICAGO, ILL., Sept. 5, 1898.
Gentlemen:—We have used your Diamond Anti-Fly on our horses this season with such success that we intend to use it every season, and strongly recommend it to all stock-owners, especially to packers and butchers, where the flies are so numerous. Yours truly, SCHWARZSCHILD & SULZBERGER BEEF COMPANY.

Circulars Free. MANUFACTURED ONLY BY **Sample 25 Cents.**

THE EDGEWOOD REFINING CO., Cleveland, Ohio.

etc., shown the value of feeding to fattening hogs, something besides those highly starchy feeds, corn and kafir. In feeding over 200 head of hogs experimentally, not a case has come up where the results were not most favorable to feeding some feed rich in protein, along with the corn and kafir.

But what is intended to be brought out in this item is not the pecuniary gain from feeding such feeds as alfalfa hay, skim milk or soy bean meal, with the other feeds, but it is the humanity of doing so. Putting a hog in a small pen and giving it no feed but dry corn and kafir and water is inhuman. Hogs so treated, when you come to the pen, will walk away as far as they can, and eye you as though they knew you were responsible for their pains of digestion, the annoying lice, and all the other unfavorable conditions of the young hog that is being starved on carbohydrates. Protein is the source of the blood, bone, hair, muscle and nerve—take away this supply, and what has the poor hog to live for? Their hair drops out, their belly bows up as well as the back bone; great rough wrinkles of hide seem to work out on the tail, but instead of wrinkles working out, the body has drawn up and left the hide, like the insect that pupates in one end of the worm, as we say. The hog has a cough, and undoubtedly if such a hog could read and had access to our family papers, and not the experience of many persons, it would send for remedies for a dozen different complaints.

Dumb animals have a spirit, as we say, as well as human beings, and if this element of their nature is destroyed by unfavorable circumstances and conditions, they are subject to the same moods; and it will require a great effort to bring this spirit back, yet until this is done they will not grow or fatten. If the hogs are fed the proper feed and treated kindly, they come to meet you when you approach the pen, and have an appearance of perfect content, which is as different from the above described condition as day is from night.

Feed your hogs a variety, and make sure that you know that the feed contains the proper elements to insure a good, healthful condition.

J. G. HANEY.

Kansas Experiment Station.

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—The offering of butter on Monday's Elgin Board of Trade aggregated 22,440 pounds. Bidding opened at 17 cents and advanced to 18 cents on call.

At this price 7,140 pounds were sold: 3,000 pounds remained unsold, with 18 cents bid and 17⅝ cents was declined for 12,300 lbs. The market was reported steady at 18 cents.

The sales made were:

Factory.	*Pounds.*	*Price.*
Oregon	4,800	18c.
Triumph	900	18c.
McConnell	1,400	18c.
Total	7,140	

The sales for the corresponding week of the three preceding years were as follows:

July 11, '98, 19,745 pounds of butter sold at 16c.
July 12, '97, 15,900 pounds of butter sold at 14½c.
July 13, '96, 52,980 pounds of butter sold at 14¼@15c.

The New York market was reported steady at 18½c.

H. C. B.

Elgin, Ill., July 10, 1899.

DAIRY MARKETS.

ELGIN, Ill., July 10—Three hundred and seventy-four tubs butter offered; 119 tubs sold at 18c. Committee reported market steady at 18c.

CHICAGO, Ill., July 10—Butter—Creamery, extra, 17@17½c; firsts, creameries, 16@16½c; seconds, 14@15c; dairies, selections 15@15½c; No. 1, 14c; No. 2, 13c; extra ladles 12@13c.

Eggs—Fresh, at mark, cases returned, sold at 11@1 ½c; loss off, cases returned 12½c.

Cheese—Full cream, Twins, new, good to choice, 8¼@8¾c; Young America, 8¾@9c; Swiss, 12@13½c; Limburger, 7@8c; bricks, 7¾@8¼c.

Bran—In light supply and prices higher, with sales at $11.75 per ton.

Cattle—Beef cattle sold about 10c higher than the close of last week and as high as the high time of last week, quality considered. Sales were at $4.95@5.90, largely at $5.35@5.55; against $5.20@5.50 for the bulk last Thursday, $5.30@5.60 on Wednesday, and $5.25@5.50 on Monday of last week. Sales included 1,100@1,331-lb. stillers at $5.35@5.75, and 1,412@1,536-lb. Westerns at $5.40@5.75. Texas steers sold at $4.65@5.05. The cow market was weak to lower.

MILWAUKEE, Wis., July 10—Butter—Creamery—Fancy prints, per lb., 17½c; extras per lb. 17½c; firsts per lb. 16@17c; seconds per lb. 14@15c; imitations per pound 14@15c. Dairy—Selections per lb. 14@15c. Market a shade off, wants being less urgent; receipts 16,598 lbs.

Cheese—American Full Cream—New, choice to fancy 8½@9½c. Brick—New, per lb., choice 8@8¾c. Limburger—New, choice per lb. 8@8¼c. Swiss—Drum, choice 12½@13c; new block choice 10@10½c.

Eggs—Fresh per doz. 12c, loss off cases returned.

AVOCA, Wis., July 10—Offerings on the Lone Rock and Muscoda Dairy Board to-day were 740 boxes Twins, all sold at 8@8¼c; market firm.

FOND DU LAC, Wis., July 10—Offerings to-day 600 Twins and 590 Daisies; market active at 8½c for Twins and 8¾c for Daisies.

PLYMOUTH, Wis., July 3—Cheese—Sales to-day, 1,250 Twins at 8c; 75 Young Americas 8¼c; 720 Young Americas at 8⅜c, and 240 at 8½c.

CHILTON, Wis., June 28—Cheese—The sales reported were 500 Twins at 8c, and 640 cases Young Americas at 8¼c.

APPLETON, Wis, June 29—Cheese—The offerings on the call board, today, were 531 Twins. All sold at 8¼c. Market active.

BRILLION, Wis., June 30—Cheese—Sales of cheese on Brillion Dairy Board today, were 1,427 Daisies and 835 Twins at 8⅛c; 327 cases Young Americas 8¼c.

HORTONVILLE, Wis., June 29—Cheese—Offerings on Board today, were 666 Cheddars and 1067 Twins. Sales, 240 Cheddars at 8¼c, 137 Cheddars at 8⅜c; 157 Twins at 8¼c; 653 Twins at 8⅜c. Ruling price: Cheddars 8¼c, Twins 8⅜c. Market active.

SHEBOYGAN FALLS, Wis. July 5—Fourteen factories offered 1,195 boxes of cheese on the call board to-day, and all were sold as follows: 660 cases of Young Americas at 8⅝c; 240 boxes Twins at 8⅜c and 95 Daisies at 9c.

MANITOWOC, Wis., July 5—Offerings of cheese at Dairy Board to-day were: 600 boxes Daisies, 135 boxes Twins, 888 boxes Young Americas. Sales were, 400 Daisies at 8c; 200 at 8¼c; Twins, 8@8¼c; 740 Young Americas, at 8c; 140 at 8¼c.

PHILADELPHIA, Pa., July 10—Butter—Solid-packed separator creamery, extra, 18½@19c; creamery, firsts, 18c; seconds, 16@17c; imitation creamery, extra, 16c; firsts 15c; seconds, 13c; ladle-packed, extra, 14@14½c; firsts 13½c; seconds 13c. Print butter, creamery, extra 20c; firsts 19c; seconds 17@18c.

Eggs—Pennsylvania and near-by, 14c; Western 14@13½c; Southwestern, 14c; Southern 12c.

ST. LOUIS, Mo., July 10—Butter—Quiet, creamery 15@18½c; dairy 12@15c.

Eggs—Steady; 9½c.

KANSAS CITY, Mo., July 10—Butter—Creamery, 14¼@16½c; dairy 13c.

Eggs—Fresh 10c.

CINCINNATI, O., July 10—Butter—Steady, 19c.

Eggs—Quiet, 9½c.

Cheese—Firm; good to prime Ohio Flats, 8½c.

BOSTON, Mass., July 10—Butter—Market quiet, 18½@19c.

Cheese—Steady, 8½c.

Eggs—Quiet; 15c.

PHILADELPHIA, Pa., July 10—Butter—Creamery 18½@19c; prints 20c. Market firm.

NEWARK, N. J., July 10—Butter—Market steady 18½c for fancy Elgins. Receipts liberal.

WASHINGTON, D. C., July 10—Butter—Market steady; extras 19c; firsts 18c.

NEW YORK, July 10—Butter—Creamery, Western, extras, 18½c; firsts, 17½@18c; state extras, 18½c; firsts, 17½@18c.

Cheese—State full cream, large, colored or white, choice, 8c; small, 8½c.

Eggs—State, Pennsylyania, and Western, 15@16c.

BOONEVILLE, N. Y., June 30—The cheese market on the Booneville Board to-day was firm. The buyers present were Messrs. McLeod, Miller and McAdam. Sales: Thirteen lots large, 859 colored, 8c; one lot large, 100 colored, 8⅜c; five lots large, 250 white, 7⅞c; five lots small, 260 colored, 8⅜c.

NEW YORK MARKET.

NEW YORK, July 8—Butter—Receipts for the week, 58,103 packages. Exports for the week, 987 packages.

There is a moderate speculative demand for strictly extra creameries at 18½c and price is firm, as the proportionate receipts of that grade is comparatively so small that even a fraction above 18½c has been reached on some favorite lots; but below that grade of which the main bulk of the receipts consists, the demand is light and trade unsatisfactory. Local trade is buying only enough to supply their immediate wants and exporters are about out of the market. We note sales of fine creameries at 18@18½ and really good ones at 17½@17¾c. Fine dairy butter sells quick at our quotations, while off qualities are sold down to 14@16c. Market closes with more offerings of all grades and easier prices would be accepted for any long lines of butter. We quote:

Creamery, extra, 18½c; medium, 17½@18¼c; poor, 15@16c. Dairy, extra, 17½c; medium, 16@16½c; poor, 14@15c. Ladle, extra, 14½c; medium, 14@14¼c; poor, 13@13½c.

Cheese—Receipts for the week, 38,502 boxes. Exports for the week, 13,214 boxes.

Cheese are quoted in this market at 8@8¾c for finest, and yet they can't be bought for less than 8¼@8½c and some receivers are asking even more. A good many of the cheese arriving this week went into cold storage for later markets. We note sales of fine, large size at 8¼@8¾ and small cheese at 8¾@8⅝c. Sales in Catteraugus County this week are reported at 8¼@8¾c. Market closes firm. We quote:

Full cream, small, extra, 8½@8⅝c; medium, 8@8¼c; poor, 6@7c; large, extra, 8¼@8½c; medium 7¾@8c; poor, 6@7c. Part skimmed, extra, 7¾@8c; medium, 6½@7c; poor, 4@5c.

Eggs—Receipts for the week, 56,029 cases. Receipts continue heavy and a large proportion of the arrivals show more or less defect from the heat. Prices however for fancy stock is firm and sales liberal. We quote:

N. Y. State and Pennsylvania, per dozen, 15@16c; northern and western, best marks, 15@15½c; South-western, 13½@14½c.

177 Chambers St. DAVID W. LEWIS & CO.

BALTIMORE, Md., July 10—Butter—Market steady; creamery, separator, extra, 20c; extra first, 18@19c; creamery, first, 17@18c; creamery, imitation, extra, 15@16c; ladle, extra, 14@15c; Western, store-packed, 11½@12¼c.

Eggs—Market weak; strictly fresh, 11½@12c.

BALTIMORE MARKET.

BALTIMORE, July 6, 1899—Butter—Receipts of separator creamery have been quite liberal; particularly is this the fact with respect to regular marks from the Elgin district, which it is pleasant to learn have again graded satisfactory. It has been a common experience with nearly all receivers that, since our last issue, there has been freer buying by the distributors and cutters of this variety of butter, presumably to make good the deficiencies in the supply of near-by creamery—deficiencies in quality and quantity, the latter largely the effect of an increased demand for cream in its unmanufactured state for other uses, principally the production of "frozen victuals" for patriotic observances or cooling purposes. June has come and gone, and yet there has been little or no stocking up by speculators of the one article that has heretofore been deemed essential to an intelligent prosecution of the butter business; and to the thoughtful observer it seems to mark the "passing" of June creamery. There were two principal reasons assigned for not buying it, as it was being produced.; the one was, it was not considered cheap; and the other, that later on the product of the same creameries would be for sale for less money, and be fully as desirable. Gathered cream and ladles have been in lighter receipt, with a demand fully equal to absorbing the offerings. Out-of-town trade has been very light; exporters have no orders for creameries. Storepacked is in light receipt, with a quick demand for all grades.

Creamery Separator, extras, 19c; firsts, 18c; seconds, 17c. Gathered Cream, extras, 18c; firsts, 17c; seconds, 16c. Ohio, extras, 18c; firsts, 17c; seconds, 16c. Imitation, extras, 16c; firsts, 15c; seconds, 14c. Iowa & N. W. Ladle, extras, 14c; firsts, 13c; seconds, 12. Ohio & Indiana Ladle, extras, 14c; firsts, 13c; seconds, 12c. Ohio store-packed, extras, 12½@13c; firsts, 12c. W. Va. packed, extras, 12½@13c; firsts, 12c. Creamery Blocks (2 lbs.) extras, 21c; firsts, 20c; seconds 19c. Prints (½ lb.) extras, 21c; firsts, 20; seconds, 19c. Md. Va. & Penn. Prints, extras, 19c; firsts, 18c; seconds, 16@17.

Eggs—While there has been no great increase in the receipt of eggs so far this week, the supply is more than equal to the demand, and there is some accumulation of shock, even at the lower prices prevailing. We would advise that you exert the greatest care in the selection and shipping of your eggs. As is usual at this season of the year, the quality is unsatisfactory; the best is none to good, and buyers will take nothing, but the best fresh stock: market quiet and barely steady at 12½c.

Cheese—The receipts are ample for the demand; the market quiet; demand fair.

N. Y. State Cheddars, fine, 8¾@9c; choice, 8½c; fair, 8@8¼c. Flats, fine, 9@9¼c; choice, 8½@8¾c; fair, 8¼c. Small, fine, 9¼c; choice, 9c; fair, 8½c. Ohio Flats, fine, 8½@8¾c; choice, 8@8¼c; fair, 7½@8c. Picnic, fine, 9¼@9½c; choice, 9c; fair, 8¼@8½c. Skims, fine, 7½@7¾c, choice, 6@6¼c; fair, 5@5½c. Swiss Cheese, fine, 13½@14c; choice, 12@13c; fair, 11c.

301 Exchange Place. G. M. LAMB & BRO.

Latest quotations for fancy creamery: New Orleans 18½@19c; Buffalo 19c; St. Paul 17½c; Minneapolis 17c; Detroit 19c.

LIVERPOOL, July 10—Butter—Good United States 62s.

Cheese—American finest white and colored 42s.

FOREIGN MARKETS.

BOSTON, July 8—Cable advices of this date from the principal markets of Great Britain to Geo. A. Cochrané give butter markets as all the turn easier. The most pronounced drop is in Danish which has fallen to 20@21c, Irish 20@20½c. Finest Canadian in boxes is selling at 18½@19c. Low grades of butter are working into better shape and there is a better inquiry for fine ladles that would bring 14½@15c. Weather conditions are more favorable with pastures much improved all over Europe.

Cheese markets are all steady with the demand fully equal to the supply, which has prevented any accumulations. The consumption is very large. Finest American and Canadian selling at 9@9½c, white having a slight premium over colored.

THE

SEPARATOR QUESTION.

An "Alpha" disc separator and savings which almost insure success?

Or a "hollow-bowl" separator and losses which mean ultimate failure?

Which promises best? Which is "cheapest?" Is there much ground for hesitation? No!—not in your case nor that of any other user of a cream separator.

The "Alpha" disc system makes all the difference imaginable—it marks the line between success and failure in up-to-date creamery operation.

De Laval catalogues illustrate separator principles and differences in detail. They may be had for the asking—"Dairy" or "Creamery."

The De Laval Separator Company,

WESTERN OFFICES: Randolph & Canal Sts., CHICAGO.
GENERAL OFFICES: 74 Cortlandt Street, NEW YORK.
BRANCH OFFICES: 1102 Arch Street, PHILADELPHIA.

READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

For Sale—Creamery located in good dairy country. Three railroads and express companies. Market convenient. Address "CREAMERY," Lowellville, Ohio. 21-4

Tamworths, ready to wean, $10 each, or $12.50 delivered. Hermanville Farm, P. E. I., Canada. 32-52

An up-to-date Farmer of good character and standing, who understands his business, would like a situation as foreman or manager by January 1st. Best of references. Address, BOX 204, Framingham, Mass.

Wanted—Position as forman, buttermaker, or herdsman on dairy farm. Single man, 35 years of age. Taken two courses in Agricultural College. 10 years experience. ABE SAUERS, Bristol, Tenn.

For Sale—Holstein-Friesian Cattle. Three cows, eight heifers and three young bulls, all richly bred, beautifully marked and of fine individuality. Write for prices and particulars. A. T. CORDRAY, London, Ohio.

Married man wants position on dairy or stock farm to take management or otherwise. Can run separator or make butter if necessary. Address H. J., care of HOARD'S DAIRYMAN.

Excursion Tickets to the Great American Exposition, to be held at Omaha, Neb., until October 31, 1899. Via the North-Western Line, will be sold at reduced rates. from certain stations on specified dates. For rates, dates of sale and limits of tickets apply to agents Chicago & North-Western Railway. 22-sp

Excursion Tickets to Freeport, Ill., Via the North-Western Line, will be sold at reduced rates, from stations within 75 miles, July 18 to 21, inclusive, limited to July 22, inclusive, on account of the Horse Races. Apply to agents Chicago & North-Western Railway.

Exceptionally Low Rates to Indianapolis, via the North-Western Line. Excursion tickets will be sold at greatly reduced rates from all stations. July 18, 19 and 20 (but not for trains arriving Chicago before July 19 or later than July 21), limited to August 20, 1899, inclusive, on account of National Convention Epworth League. Apply to agents Chicago & North-Western Railway. 21-2

Excursion Tickets to Madison, Wis., via the North-Western Line, will be sold at reduced rates, from stations in Wisconsin and certain stations in Illinois, July 17 to 31, inclusive. limited to August 1, inclusive, on account of Monona Lake Assembly. Apply to agents Chicago & North-Western Railway. 21-2

Relation of Water Supply to Animal Diseases.

[United States Farmers' Bulletin, No. 97.]

About three-fifths of the animal body is water, and while water is not strictly a food in itself, no food can be assimilated without the aid of water, large quantities of it being required to carry on this process.

According to a bulletin of the Indiana Station:

"The horse requires from 64 to 80 pounds, or eight to ten gallons per day, a gallon of water weighing eight lbs. During the month of February and March, five horses drank from 48 to 60 pounds, per head, when not at work, and from 62 to 84 pounds, while at work. Forty-four per cent of the water was drunk in the forenoon, and 56 per cent in the afternoon.

"Cattle drink more than horses. During the period above referred to, cows not giving milk drank 78 pounds, and cows in full flow of milk drank 112 pounds, per day. The largest drink was 122 pounds, and the greatest amount taken by one animal, in one day, was 176 pounds. The Utah Experiment Station found that steers, feeding upon dry feed, required 83 pounds of water, per day, while those fed upon green food consumed only 33 pounds per day. Cattle drank 72 per cent of water in the morning, and 28 per cent in the evening."

Pigs, fed corn and skim milk (3 pounds per day) drank 2.65 pounds of water per day; those fed wheat and skim milk, 5.2 pounds; those fed corn, wheat and skim milk, 3.9 pounds; those fed soaked wheat and skim milk 5.3 pounds. These figures indicate, as in the experiments with steers at the Utah Station, that the amount of the water drunk is influenced to a considerable extent by the character of the food.

"No attempt has been made to determine the quantity of water needed daily for sheep. * * * They drink comparatively little water while upon pasture. They can endure privation as regards water far beyond other domestic animals. This has led to the belief, common among farmers, that sheep do not need water and that dew is sufficient. This is a serious mistake, and accounts for the loss of many hundred lambs in this state, every year.

"The number of times an animal will drink during the day, when allowed full opportunity, is not known, but is indicated in a general way by the stomach. The stomach of the horse is small and, as might be supposed, does not require much water at a time, but often. The stomach in cattle is very large, and rumination (chewing the cud) is performed. This necessitates saturating the food with water before rumination can take place, and probably explains why so much water is drunk in the morning."

The above facts make it clear that we may expect a close and important relationship between water supply and disease in domestic animals, and this fact is most strikingly demonstrated when the supply is insufficient, or is contaminated with matter which causes disease.

"The diseases which arise, as a result of supplying water in insufficient quantities or not providing water in accessible places, are sporadic in character; that is, affect only an occasional animal, or a few in a herd or flock. Probably the most serious disease having such cause is mad itch in cattle. This occurs especially in the fall of the year, when the cattle are upon dry pasture, or when turned in upon a dry stalk field. It may occur at other times, and also be due to other causes, but without doubt ninety per cent of the cases occurring in this state are directly traceable to this cause. Sheep also suffer from impaction and constipation, and large numbers die for want of proper water supply. Hogs, especially young ones, often succumb from like treatment. Horses, probably, suffer least loss, because they receive the greatest care in this respect, but, no doubt, many cases of colic, impaction, and constipation are traceable to this source."

The losses that arise from an insufficient water supply are small compared with those caused by water of an improper character. Water which comes from deep wells, properly protected, is free from disease germs; that, however, which comes from ponds, ditches, and streams may contain such germs. "Not all surface waters are dangerous, but all are more or less exposed to infection, and may become dangerous at any time."

Careful investigation has shown that hog cholera has been largely disseminated in Indiana by contaminated streams, thus bearing out the conclusions from investigations by the Bureau of Animal Industry of this Department that "perhaps the most potent agents in the distribution of hog cholera are streams. * * * The first step to be taken in the prevention of hog cholera is the securing of a wholesome water supply."

There are numerous parasitic diseases to which all animals are subject. Water is necessary to the growth of these, and is an important carrier of them. Such parasitic diseases as twisted stomach worms, nodular disease, paper skin, liver fluke, and lung worm of sheep, and worms in hogs, horses and cattle, are largely due to surface water. "Pure water from deep wells is the preventive."

What Does Milk Cost?

Figuring the Financial End of the Dairy Business.

There is probably no farming question as to which there is so wide disagreement among farmers, as there is about the cost of milk. It undoubtedly costs more in winter than it does in summer, and this was especially true under the old time system of feeding on dry hay and cornstalks, with sometimes a little grain for variety, which, however, usually went to make fat on the body rather than to increase the milk flow. There was no inducement in those days to have cows calve in the fall, for the fresh flow came at a season when it was almost impossible to keep it up. Milk is always dearer in winter than in summer, but under these conditions the slightly increased price did not pay the extra cost, and all the winter made milk had to be sold at a loss.

Now, however, a farmer who has a basement barn and silos to ensilage his corn fodder, can have cows drop their calves in the fall with some confidence that the winter product will pay its cost. Corn fodder is so much cheaper than is pasture on high priced land, that if it can be given in succulent form and if cows can be protected from winter's cold the w inter's milk does not cost any more than that made in summer, where the main dependence is on pasture. We believe that good pasture in June will bring more milk from a new milk cow than will any other feed. But that is not saying that even then it is the cheapest feed. It must be remembered also that June pasture fills out only a small part of the summer.

The grass is sappy and innutritious in May, and by July or August it either grows hard and woody or dries up so that cows will not eat so much of it, and what they do eat will not make so much milk. So great is the need of extra feed for cows at this time that corn drilled for fodder is often cut before it has even got into blossom, and when it, of course, has very little nutrition. So soon as corn matures sufficiently, that will furnish a ration that will materially increase the milk flow in cows at pasture. Indeed many of the best farmers put their cows in darkened stables during August heats, partly to protect them from flies. They find that entire reliance on soiling with green corn or with clover makes a larger milk flow, and makes it more cheaply than does reliance on pasture, even when corn is cut and fed daily as an adjunct to it.

This, we think, pretty nearly proves that, considering results, the winter feed of cows costs less than it does while they are at pasture. Most farmers deceive themselves into thinking that their summer pasture costs nothing, because they expend neither money nor labor to secure its product. The cow is turned in, eating with one mouth, but all the time trampling the tender grass with four feet, soiling the grass, besides more or less bruising it and injuring its roots. If the pasture is clover, this injury is so serious that stock ought never to be turned into a clover field until it is nearly ready to blossom. Until this time, clover is about the poorest feed that can be offered to a cow. But turn a cow into a field of clover when it is in blossoms, and what will be the result? She will trample through it, biting off the clover heads and soiling or destroying fully twice as much as she eats. If the same clover were cut and fed green to the cow, she cannot separate the heads from the stem so well and will eat the whole of it. In this way three times as much feed will be got from an acre of clover as can be secured by pasturing. Some of the clover will be soiled so that the cow will not touch it through the remainder of the season.

Every farmer who has pastured clover, knows that toward fall, while most of the clover will be eaten down almost to the roots, there will be a considerable portion that has grown hard and woody, so that it has little nutritive value. When the clover is eaten off early, the second growth promptly springs up and is both palatable and nutritious. That is what grows up after the first crop has been cut for soiling or for hay. A second, third and even fourth crop of clover may be grown if the soil is rich enough, and each one will be more nutritious than the first. This repeated cutting of clover is far better for the root growth, than pasturing it can be, for in pasturing, the constant trampling of the ground hurts the plant and lessens both its roots and top growth. In short, clover will usually produce, not only three times as much feed when cut with a scythe or mower, as when pastured, but it is nearly or quite three times as much benefit to the land. When the clover is cut, more or less leaves fall upon the soil, and it is the rotting of these that doubles and trebles the growth that the clover would otherwise make. The cow returns only the excrement from the clover she eats, but that is not in condition to help the clover growth materially, the same season.—*Boston Cultivator.*

The Size of the Silo.

Until quite recently the idea has been to build the silo just large enough to afford six months feeding, but now there is an enlargement of the plan, as it is found by exhaustive trials, that silage in summer is the most effectual soiling crop yet tried, and surest. The man who has silage in summer, to feed with pasturage, is independent of the feed seller, and nothing will hold the cows up so from shrinkage. So there is a larger planning, more silage capacity, either in larger silos or in smaller ones, now that the tub silo is so much in evidence.

The old allowance of four and one-half tons per cow, allowing for wastage, is now made larger, and six tons per cow is supposed to be about right, so as to give her a ton and a half in the midsummer. The capacity of the square silo is quickly ascertained, by estimating that a cow will need a cubic foot of silage a day. This for 180 days would be a little over four tons, and forty-five pounds to the foot would make it necessary to provide about 200 cubic feet for each cow; so multiply the number of cows by 200 and build the pits to hold correspondingly. In round silos the figuring is different, and as a circle has never as yet been squared, we append a table figured out for all sizes of round silos.

Diameter of Silo.	*Height of Silo.*			
	20 ft.	22 ft.	25 ft.	30 ft.
10 ft. tons capacity.....	31	34	40	47
12 ft. " "	45	49	56	65
14 ft. " "	63	68	77	90
16 ft. " "	80	90	105	130
18 ft. " "	100	110	125	150
20 ft. " "	125	135	155	185
22 ft. " "	145	160	180	215

Silo costs, depend upon location, cost of lumber, labor and all such items, as to time and place. In general terms, a silo should be built square, and outside, for somewhere near $1 a ton storage capacity. Inside the barn, 50 to 60 cents per ton, and a round one may be built for from 40 cents to $1.00 a ton, though some have cost full $3.00, and all styles for that matter, says John Gould in *Ohio Farmer.*

Rules and Regulations of the Dairy Department of the Wisconsin State Fair.

We have received copies of the 1899 premium list of the Wisconsin State Fair to be held in Milwaukee, Sept. 11th to 15th inclusive. Mr. J. W. Thomas, of Anson, Wis., is the Superintendent of the Dairy Department, and has secured the following liberal assignment of premiums:

For creamery butter, to be exhibited in 60-lb. tubs, $230.00.

For dairy butter, to be exhibited in 8-lb. packages, $140.00.

For print butter not less than 6 lbs., $32.00.

For granulated butter in two quart jars, $18.00.

For butter in novel forms not less than 8 lbs., $15.00.

For factory Cheddar cheese, in box not less than 60 lbs., $100.00.

For Flats or Daisies, two in a box, $125.00.

For Young Americas, weighing not less than 10 lbs., $20.00.

For Brick cheese, 60-lb. case, $75.00.

For Swiss cheese, not less than 60 lbs., $75.00.

We print below the published rules, which will govern dairy exhibits, and if further information is desired, write Superintendent Thomas, at Anson, as above:

RULES.

Persons, after making entries with the Secretary, can ship their exhibits to the Superintendent of this department, express prepaid, marked, "State Fair Park, Milwaukee, for Exhibition Dairy Hall."

The superintendent will receive the same, attend to its exhibition, and if so directed by owner, dispose of the butter or cheese at best possible advantage and remit proceeds to exhibitor.

When entry is made, state, if you wish, exhibit sold or returned, giving post office address and express office.

Mark exhibits with removable tags, giving name and address of owner, but do not mark packages with name of exhibitor, as this must be withheld from Judge.

Butter and cheese will be kept separate. A large glass refrigerator, well supplied with ice, constructed for exhibition purposes, has been provided for each.

No brand or other distinguishing marks will be allowed to remain on any article entered in this department prior to or during judging.

Butter from the milk of a single herd of cows, owned by one person, partnership or corporation, and made on the premises where the milk is produced, shall be classed as Dairy Butter. Butter from the mixed milk or cream, gathered and brought to a factory from two or three herds, owned by different persons, partnerships or corporations, and made in a factory, shall be classed as Creamery Butter.

All dairymen, creamery men, commission men and manufacturers of dairy implements are cordially invited to make Dairy Hall their headquarters.

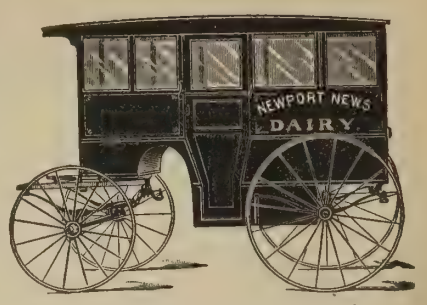
Manufacturers, dealers and inventors will be welcomed with their implements. Every facility will be extended for making a good display.

Exhibits should be billed so as to reach Milwaukee on or before 12 o'clock noon of September 12th. Exhibits arriving on Sunday will be promptly taken to the refrigerators on the grounds.

Butter and cheese will be judged on a scale of 100 or perfection, according to the standard adopted by the markets of Chicago and New York, as follows;

BUTTER.

Flavor	45
Body	25
Color	15
Salt	10
Style of package	5
	100



CHEESE.

Flavor	45
Texture	30
Color	10
Salting	10
Style of make-up	5
	100

All premiums in this department, unless otherwise noted, will be awarded on the pro rata plan, and 90 points will be the minimum for all awards on creamery butter and cheese, and 88 points the minimum for dairy butter.

The premium will be divided among the scores above the stated minimum, on the following basis:

The World Cannot Show Its Equal

In STYLE, CONVENIENCE and DURABILITY.

Body hangs but 17 inches from ground, and turns can be made in its own length. Sold direct to Dairyman at bed rock prices. For description and price address,

THE NATIONAL WAGON CO.,
Chillicothe, Ohio.

Creamery butter and cheese scoring over ninety points will be entitled to one share of pro rata for each point scored above 90 to 95 inclusive, and two shares for each additional point scored above 95.

Dairy butter scoring over 88 points will be entitled to one share of pro rata for each point scored above 88 to 93, inclusive, and two shares for each additional point scored above 93.

Provided that the maximum amount awarded to any one exhibitor of creamery butter, shall not exceed $30.00, and the maximum amount for dairy butter shall be $15.00, and for print butter, $8.00.

The maximum premium for Cheddar or Twin cheese shall not exceed $25.00, and for all other kinds of cheese $15.00.

When the award on any one entry shall amount to the maximum limit, the awards on all other entries in competition may be pro rated according to merit as compared with the highest,

By this method of awards all exhibits of high merits will receive a certain proportion of the premiums offered, according to the score, and as the awards are all based on the score, the Judge will carefully review his work that no mistake may happen, and a mistake in judgment of one or two points will only affect the premium two or three dollars at most, and it makes it impossible for three or four exhibitors to take all the money offered.

All manufacturers of butter or cheese are most cordially invited to exhibit samples of their products that this department may well represent one of the great industries of the state. The State Board of Agriculture fully recognize the importance of the dairy industry, and expect another year to be able to offer premiums in each branch of the business according to its magnitude.

It is the desire of the Board to make this department as instructive to the exhibitor as possible. All the judges will be the very best experts to be had, and the superintendent will be supplied with duplicate score cards for each entry, one to be filled out and signed by the judge, who shall also make a note on the card of any special defect in the exhibit, stating what it is. As soon as the Judge has completed his work, the Superintendent shall see that the duplicate cards are carefully copied and compared with the original, then put in a sealed envelope, properly addressed, and mailed to the exhibitor.

No butter or cheese should be previously scored by an expert.

Milk.—Bacteria.—Cream Mark.

ED. HOARD'S DAIRYMAN:—I am buying milk from one of my neighbors to help out my summer trade. After setting and skimming, we had some skim milk to-day for dinner and I noticed that it was sour, it was yesterday morning's milk and is sour at about 30 hours old, which my wife says never happens to the milk from our cows. Both of his cows have had calves since mine have. The same milk from my cows, set under same conditions, same age, etc., is perfectly sweet now. Why is it? Is it the bacteria in his milk, and is there danger of getting it in my milk utensils?

I had my milk tested at the experiment station and it tested 4.6 per cent butter fat. I was telling one of my neighbors, who runs a milk route, about it and he says: "Is that all, why, you can't sell milk in Newport unless it tests 12½ per cent." I tried to tell him the difference but I gave it up and thought I would wait till I knew what I was talking about. I knew he did not know what he was talking about and I was sure I did not.

I have seen quart milk bottles with a mark near the top marked 12½ per cent or "standard." What does it mean? J. E. K.

South Portsmouth, R. I.

The souring depends entirely on the cleanliness of the milk utensils, the temperature at which the milk is set, and also whether the milk is aerated and thoroughly cooled.

There are bacteria in all milk, in yours as well as in that you buy. The time of souring, depends on the number present in the milk; the fewer they are the longer the milk will keep. Dirty surroundings will cause them to multiply very quickly and in immense numbers; the result is that the milk sours very rapidly. If you do not have facilities for keeping the milk cold, pasteurization is the best remedy.

Milk containing 4.6 per cent of fat, is of exceedingly good quality and is considerable above the average. The legal standard in Rhode Island is 2.5 per cent fat. The mark on the bottles is supposed to indicate the amount of cream in the milk and is only an idea of the bottle manufacturers. There is no law regarding it.

Artificial Flavor in Oleomargarine.

Closely associated with the application of bacteriology to butter making, is its application to the preparation of artificial butter and various oleomargarine products. This subject, however, may be passed over with only a word. In certain European countries, especially in Holland, oleomargarine is made in very large quantities. The largest factories in the world are located in Rotterdam. In these factories the use of pure cultures has for some time been adopted with almost absolute uniformity. The shrewd business men who manage these factories have thoroughly learned that if they wish to obtain in their products a flavor imitating that of butter they are obliged to use bacteria to give them this flavor. They therefore buy the artificial pure cultures and inoculate them into large quantities of pasteurized milk in essentially the same way that the butter maker inoculates them in his cream. They allow this milk to stand in a warm place for a length of time, which will produce the proper amount of souring, and then this ripened milk is mixed with the fats, and the mixed oils made into margarine products. The result is that a flavor of butter which is, of course, derived from bacteriological products of the souring milk, is imparted to the margarine. All of the better grades of artificial butter are made in this way.

The margarine factories use various kinds of pure culture and experiment upon them with a good deal more care, and know much more about their use than do the butter-makers. Butter makers make comparatively small quantities of butter, while oleomargarine factories make their product in very large quantities, and their market is much more dependent upon the grade of their product than is the market for butter. Some of these oleo factories have their own bacteriological laboratories, where experiments are going on constantly, and where they can obtain their own pure cultures and make use of the very best results of the most recent advances in bacteriology. The wide application of bacteria in the manufacture of oleomargarine products, should be a lesson to the butter maker. PROF. H. W. CONN.

Storrs' College Report.

The Minnesota Anti-Preservative Law.

The legislature of Minnesota recently passed the following law:

Section 1. Any person, firm or corporation who shall sell or offer for sale, or consign, or have in his possession, with intent to sell to any person or persons any milk, cream, butter, cheese, or any other dairy products, or who shall deliver to any creamery or cheese factory, milk or cream to be manufactured into butter or cheese, to which has been added any preparation in powdered or liquid form, known as preservatives, or any other compounds containing antiseptics, shall be deemed guilty of a misdemeanor, and upon conviction therefor be punished by a fine of not less than twenty-five or more than one hundred dollars, for each and every offense.

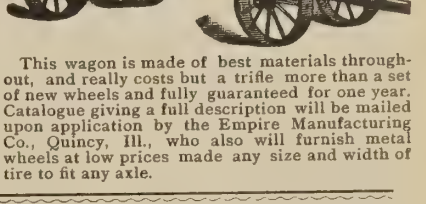
This shall not be construed to prohibit the use of salt in butter.

Section 2. The state dairy and food commissioner and his assistants, experts and chemists, by him appointed, shall be charged with the proper enforcement of all the provisions of this act.

Section 3. In all prosecutions under this act the costs shall be paid in the manner now provided by the law, and the fines resulting therefrom shall be paid into the state treasury and placed to the credit of the state dairy and food commissioner's fund.

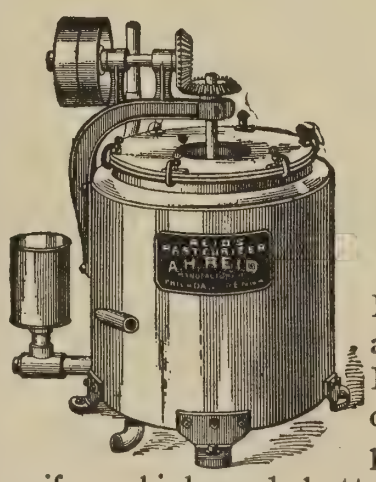
Section 4. This act shall take effect and be in force from and after its passage.

The Cow Is a Law Unto Herself.



Most farmers have been led to believe that the per centage of fat in the milk is determined largely by the quality of the food given to the cows. On the other hand, the results of nearly all the scientific experiments and tests go to show that the kind of food fed to the cow has little influence upon the fat in the milk, but that everything depends upon the cow. There are some cows that seem to be born with the ability to produce milk rich in fat, and food of any kind will keep up this supply. Of course, starving and gradual degeneration of the animal will decrease the supply of milk and consequently the quality of fat. But with fair care and food the percentage of fat will remain good and quite constant.

This brings us to the important matter that all dairymen must consider. The cow is a law unto herself She is created a milking machine that is valuable to her owner, or she is a poor milker whose existence on the farm is unprofitable to the farmer. Experiments, conducted in the most careful manner, have failed to increase the fat of a cow's milk to any material extent. Under forced feeding, the fat percentage might be increased, but it would only be temporary. Some seasons of the year the percentage of fat is much higher in one cow's milk than at another time, and this change should not be attributed to the food. It is due to natural causes that cannot be easily explained. So we come to the conclusion that while breed and the individual cow may not be everything, it certainly is more than half the question. Food plays an important part in keeping the cows up to a standard of health and functional activity; but its influence is comparatively small in determining the quantity and quality of the fat in the milk. The moral is obvious. If we expect to have good milkers, we must select cows that have a special gift for this.—*Ex.* E. P. SMITH.

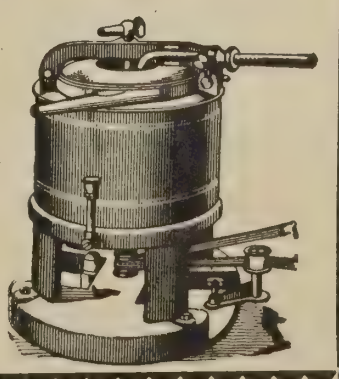


THE creamery at Warsaw, Mo., has suspended for awhile. The reason given is, "The farmers are too busy to bring in milk." This illustrates the folly of building creameries in communities where the farmers have no sort of sympathy, training or knowledge consistent with the business.

A Low Wagon at a Low Price.

In order to introduce their Low Metal Wheels with Wide Tires, the Empire Manufacturing Company, Quincy, Ill., have placed upon the market a Farmer's Handy Wagon, that is only 25 inches high, fitted with 24 and 30 inch wheels with 4 inch tire.

This wagon is made of best materials throughout, and really costs but a trifle more than a set of new wheels and fully guaranteed for one year. Catalogue giving a full description will be mailed upon application by the Empire Manufacturing Co., Quincy, Ill., who also will furnish metal wheels at low prices made any size and width of tire to fit any axle.



You Can't Deny A Fact.

Practical and personal experience with the Reid Pasteurizer is the best test of the merits of pasteurization and the strongest argument in its favor. The Reid Pasteurizer is a fact which upsets the theories of the opponents of hot skimming. The creameries that use it produce perfect cream for all purposes and make the most uniform, high-grade butter, entirely and always free from bad flavor, and undesirable odors. A fair trial of the

REID Pasteurizer

is more convincing than any amount of talk. Write at once for complete description and price and don't forget to ask for the **Reid Long Spindle Separator** book. All free by mail.

A. H. REID, 30th and Market Streets, PHILADELPHIA, PA.

And CEDAR RAPIDS, IOWA.

Growing Ensilage Corn in the Maritime Provinces.

ED. HOARD'S DAIRYMAN:—I herewith hand you replies from two other prominent dairy farmers in the Maritime Provinces on growing the corn crop. From Supt. Robertson, of the Experimental Farm, Nappan, N. S., probably one of the most up-to-date dairyman in all Canada, and while in Quebec was probably the most successful breeder of Aryshire cattle in Canada, according to results at Canadian fairs.

The second reply from Mr. Parlee, of Sussex, New Brunswick, shows that a man may be a successful dairyman without the use of ensilage, for Mr. Parlee is undoubtedly the most prominent breeder, of not only dairy cattle, but of swine, sheep and poultry as well, in the Province of New Brunswick.

No doubt in Mr. Parlee's case the soil and climate in his vicinity, as in many parts of the Province of New Brunswick is not adapted to paying crops of corn ensilage; manifestly if corn would grow paying crops, such an up-to-date man as Mr. Parlee would certainly be growing it. From Mr. Parlee's reply we can therefore conclude that in some parts of the Maritime Provinces, notably parts of New Brunswick, it will not pay to try growing ensilage corn and secondly, as in Mr. Parlee's case, a successful dairy can be carried on, and high class dairy stock can be had without ensilage corn. From the four replies received, from as many dairymen representing the three Maritime Provinces of Nova Scotia, New Brunswick and Prince Edward Island and each thoroughly representative of their calling, three of them are successful corn-growers and think highly of the feed for dairy cows. They have given the *modus operandi*—minute details of the methods, that any dairyman who, upon reading these two articles, thinks of building a silo next summer and growing a crop of corn to fill it, can adopt either of the three methods of growing the crop, Mr. Brow's, Mr. Fuller's or Mr. Robertson's. It would be well to preserve these numbers of the DAIRYMAN, for if corn cannot be made a success by either if these methods the crop cannot be grown at all in the Maritime Provinces.

Those farmers, however, who are located in a moist district like Mr. Parlee and where the soil is more adapted to the growth of hay crops need not lose courage. Like Mr. Parlee they can grow lots of roots, and these fed with hay and other green crops will be found an excellent feed for dairy cows. Thanking the gentlemen for their prompt and exhaustive replies and the readiness to which they acquiesce to furnish the DAIRYMAN with the results of their experience for the benefit of their brother farmers in the Maritime Provinces who are readers of the DAIRYMAN.

J. A. M.

I have had but little experience in feeding ensilage corn to cows. We use the turnips and mangels here mostly, as corn is hard to grow, and not a very sure crop. A few years ago, our farmers started growing corn quite extensively, and some went to considerable expense in putting in silos, but now there is but little grown, and it is usually fed off before the frost comes in the early fall.

My ration for milch cows, during the winter is, cut hay, or straw if scarce of hay, and often the chaff and tailings from harvesting machines, wet thoroughly with a mixture of ground oats, wheat middlings and turnips or mangels pulped. Quantity: I sometimes vary according as the cow will feed or take, and then as much clover hay as they will eat up clean. I find my cows do well and milk well on this ration, provided the hay is good.

Sussex, N. B. M. H. P.

While I doubt very much if corn ensilage can be made as much the principal food for dairy cows here in the Maritime Provinces, that it is a little west of us, yet I think it can and should be grown much more extensively than it is. That was my impression when I came here a year ago. I did not say much about it, feeling that it was best to give it a trial first, which I have, and am very well satisfied with the results, getting from 12 to 22 tons per acre, with the field corn averaging about 18 tons, in first-class silage stage. Of course that is only one year up to July 1st, it could hardly be a worse year for corn, but July was good. I do not wish to put myself on record as saying that the great majority of the farmers understand growing some crops better than they do corn. (It would come badly from me). Still I am much inclined to believe that with the methods of growing corn studied, instead of being condemned before being learned, that the cost of ration for our dairy cows can be lessened considerably, which is one of the great essentials in success.

It seems to me strange, to begin to write about methods of growing corn, when so much has been written by able writers, of a business so well known. I hardly know where to begin, and will likely leave out some very essential points.

I prefer a sod field manured in the fall on the grass, left as long as possible in the spring, before plowing, getting all the grass possible to turn under, (clover preferred) plowed not at all deep, very well worked up, (not extra deep.) Hills, mostly, give rather more ears than drills, sow three-fourths bushel per acre; better to harrow out three stalks than to have to dibble in one. If a shower of rain comes after planting, harrowing before up will help; as soon as it is properly up, I start a light swathing harrow, one with teeth slanting backward best, and keep that up once or twice per week, until six to eight inches high. I then start the cultivator between the rows, taking care to always go the same way, (in going the opposite way the little rootlets, that have been growing in the direction started by the last time passing through, will get broken off.) I like always to plant as near north and south as I can, and never hill up, giving the sun all possible chance to heat up the ground around the roots. By using a short whiffletree, just the width of the horses hips, keeping it up to his hips, and using a chain about five feet long to the cultivator, it can, and, I think it should be cultivated at intervals of about one week, until too high to see either man or horse, which will be three or four times.

Nappan, N. S. R. ROBERTSON.

PLAIN TALKS ON BACTERIA AS APPLIED TO FARM PROBLEMS.

[By Prof. H. L. Russell.]

Second Series No XX.

BENEFICIAL BACTERIA.

We are so accustomed to look upon the bacteria as the cause of disease, in either man, beast or plant, that it is rare that they are considered in any other light. While they not infrequently play the role of an enemy, still they often appear in the guise of a friend. To the farmer, one class of these animated beings is of special service, for by means of their activities, he is enabled to restore the fertility of soils in a way that is almost without expense to himself. It isn't often in this world that one gets something for nothing, or almost nothing. The farmer is apt to think that such a chance never comes to him, yet, in the process of nature we are to consider here, the law of compensation comes the nearest to being broken.

That the fertility of land is dependent upon the presence of certain chemical constituents in the soil, is now so well known that it may be considered axiomatic. A generation ago, our fathers thought that these broad western prairies were practically inexhaustible, that no amount of cropping could deplete the fertility of the soil to such an extent that it would require a restoration of the necessary fertilizing elements before a fair crop could be produced. It has not taken many years to convince them and their successors of the error into which they fell, for by sad experience, they have learned that the soil could not be robbed of its fertility for an indefinite period of time, without their paying the penalty in a reduced return. If wheat, rye, oats, or any cereal grain is continually removed from the soil without putting back an equivalent amount of manurial elements, the balance sheet of nature is sure to be struck, and diminished returns are then forthcoming. Science, as well as practical experience, has demonstrated that certain elements removed in the growing crop must be replaced. Nitrogen is one of the most important of these, and in some available form must be returned to the soil. The application of manures of the proper sort fulfill this need whether they are added to the soil in the form of our common barnyard manure, or in the form of a commercial fertilizer. In either case money and effort is required to put back the soil into its original condition.

Nitrogen, in the form of nitrates, or in an organic form as it is in barn yard manure, is more or less expensive substance; expensive either to buy as in a commercial fertilizer, or to make as in the case of animal wastes.

NITROGEN OF THE AIR UNAVAILABLE AS PLANT FOOD.

In the mantle of air which surrounds our globe, nitrogen exists in almost illimitable quantities, but in this condition it is a gas, a substance that cannot be appropriated to any extent by any of the ordinary cereal crops. If it were possible to utilize this great magazine of nitrogen, what an inexhaustible resource would become available. The golden sands of the Klondike would sink into insignificance compared with such a source of profit. But Nature in her laboratory has conceived of a way in which this unavoidable supply of nitrogen that exists in gaseous form in atmosphere may be utilized. She has done it by combining the efforts of two widely separated living structures of the organic world. By means of a peculiar combination between one of the lowest of animate objects, and one class of the more highly organized plants, this useless but nevertheless potentially valuable chemical substance of the air is appropiated and worked over into condition so as to become available for other forms of life.

CLOVER A NITROGEN CATCHER.

Every farmer's boy has been taught from earliest boyhood to regard the clover plant

Fancy's Harry-Tormentor **Bull Calf 10 mos. old.**
Dam, 42 lbs. milk per day; 21 lbs. 5 oz. butter in 7 days. **Price $75. Buy a Good One.** **J. P. BRADBURY, Pomeroy, O.**

Hood Farm Jerseys To head your herd you should have a bull of the very best breeding—one that will give you better dairy animals and greater profits. Write to Hood Farm, stating your needs. You will be surprised to find how easy it to get a young bull that has in his veins the best Jersey blood in the world. Write to-day. HOOD FARM, Lowell, Mass.

Introduce Milking Jersey Stock INTO YOUR HERD
by buying one of our bull calves, Our herd of 325 has been bred for milk for 17 years. Best blood, size and constitution. Selected stock. **Large English Berkshires,** all ages, at their best. Write for our "little book." **FILSTON FARM, Glencoe, Md.**

High-Class JERSEYS
The blood of Combination. (Sire of **25** in list) through Brown Bessie, (Champion Butter Cow at World's Fair), and Diploma 16219 sire of 48 in list including Merry Maiden. Young bulls, also cows and heifers bred to Recorder 29239—son of Brown Bessie. Printed pedigrees. State what is wanted. **H. C. TAYLOR, Orfordville, Wis.**

We Have Sold
SEVERAL OF The A. J. C. C. COWS advertised March 17th (see page 92), in fact we quoted prices that made them desirable. There still remain some as well bred as those sold, which we think **genuine bargains.** We also have a few heifers that will be right to breed at time of turning out to grass. For cows, write for List No. 3, giving short pedigrees; for heifers, List No. 2. **WINTERGREEN HILL FARM CO., Scottsville, N. Y.**

WILL SELL FOR $100
A GRAND-DAUGHTER OF PEDRO 3187, carrying also, Eurotas blood close through dam, besides plenty other butter blood. Five months old, solid color, extra udder; crated, f. o. b. **W. F. McSPARRAN, Furniss, Pa.**

For Sale . . . BULL CALF,
Grand-son of the great **Exile of St. Lambert 13657,** sire of 72 tested daughters, "more than any other bull, living or dead." He is thrifty and good size; solid fawn color. His dam has a butter test of 15 lbs. 8½ oz. in seven days. He will be sold cheap. **P. J. COGSWELL, Rochester, N. Y.**

St. Lambert **Jerseys,** all ages, both sexes. Some from **tested cows** at low prices. **W. J. HUSSEY,** Mt. Pleasant, Ohio.

THE Evergreen Farm Herd of A. J. C. C. Jerseys is now headed by St. Lambert of Brodhead, whose pedigree is unequaled in the northwest. We should be pleased to have any one in want of Jerseys to write us for catalogue, stating just what is wanted. N. N. PALMER & SON, Brodhead, Wis.

ST. OMER HERD
Choice lot of Exile and Signal bulls now ready for service. All stock tuberculin tested. **JOS. T. HOOPES, Bynum, Md.**

Biltmore Farms' JERSEYS.
This is a working herd of 250 of the best native and imported breeding, selected for work at the pail, constitution and individuality. All Tuberculin Tested. Above the fever line, so we can ship anywhere.
SOME CHOICELY BRED
Bull Calves
out of great cows and by the best sires, for sale at Dairymen's Prices. Also large **English Berkshires,** imported and native bred. Apply to **GEO. F. WESTON, Supt., Biltmore, N. C.**

GREEN PLAIN HERD
POLLED JERSEY CATTLE
Recorded stock FOR SALE. Inquiries promptly answered. **W. H. FORBES, Clifton, Ohio.**

Diplomas Combination 39962.
For Sale—Bulls and Heifers by him out of Fancy's Harry. Signal cows, some of them tested. Write us. **J. E. TYRRELL, Marysville, O.**

MILLER & SIBLEYS JERSEYS.
Ida's Rioter of St. L. leads all other bulls in average for 29 tested daughters, viz.: over 20 lbs. of butter apiece in a week. All full weekly tests, by eight different owners. He weighed 1,760 lbs. His dam's record, 455½ lbs. milk, 30 lbs. 2½ oz. butter (official test) in 7 days. **FOR SALE**—Grandsons and granddaughters of Ida's Rioter of St. L.; also cows in calf to his sons.

ONE YEARLING BULL
Out of a tested dam and **TWO BULL CALVES** out of large milking dams, for sale. Write for price. **W. R. THOMAS, Bellmore, Ind.**

224 First Prizes and Sweepstakes at 22 State Fairs or great Expositions. Big cows, Sound cows, Heavy Milkers and Great Butter Makers. Our Adelaide of St. Lambert gave 82¾ lbs. milk in one day, 205¼ lbs. in one month, the world's Jersey record. Many other championship records. No catalogue. Special literature sent if this paper is mentioned. No animal sold for less than $100. Lowest price for quality. Every animal tuberculin tested before sale, if desired. Also for sale, Chilwen's Ponies and Imported Shropshire Sheep. **Franklin, Venango Co., Pa.** **224**

PROSPECT HILL JERSEY HERD.
WISCONSIN PRIZE HERD.
Young Stock from **400 Pound Cows** for sale. Come and see them. **TUBERCULIN TESTED.** **F. H. SCRIBNER, Rosendale, Wis.**

Linden Lawn Farming Co., **OLNEY, ILL.**
Estab. '90. (*Capital Stock $100,000.00.*) Inc. '97. **640 ACRES.** Breeders of Jersey and Aberdeen Angus Cattle. Poland-China and Yorkshire Hogs, Pure bred Poultry. Send for our plan of Co-operative Farming and Investments C. S. MACE, Manager.

The Lone Tree Jerseys
THE largest collection of **high testing cattle** in the West, including **home-bred** and **Island cows. Fancy Jersey Cattle.
Service Bull,
PEDRO'S HANDSOME PRINCE, NO. 42794.
The cows in this herd are of the best families of milk and butter producers. We have for sale young bulls by Pedro's Handsome prince and Exile of St. Lambert 55, No. 36073, out of tested cows. Write for prices and pedigrees.

with more than usual notice. Why? Because in this plant and its allies, the farmer has a crop that taketh from the soil, and yet increaseth the same in richness. Surely, such a condition must seem anomalous, and indeed it is, but it is nevertheless true that the clover family does not deplete the fertility of the soil by constant cropping. Nay more, not only is the ground not impoverished, but what is more surprising, the fertility actually increases where this crop is grown.

How is it possible for such a condition to occur? Why are all the laws of nature apparently set at defiance with this family of plants? Practical experience long ago determined this valuable property, but it was left for recent years to unfold the mystery that enveloped this peculiar relationship.

If one digs down and removes carefully a thrifty, rapidly growing clover plant, he will find scattered over the surface of the roots, tiny nodules or swellings. The form and location of these varies much in different species, but they are generally present in larger or smaller numbers. At first glance, these wart-like proturberances seem to be an abnormal condition, and indeed for hundred of years, they have been supposed to be some disease process, the true nature of which was not known. On a vigorous healthy plant, these nodules generally exist; on a sickly plant growing under certain conditions they may not exist. Indeed the vigor of one plant is largely determined by the presence of these tiny swellings, for in these structures are to be found the tiny microbes which, living in the clover root, are able to fix the free nitrogen that bathes all nature about us. No story of fairy land can be more interesting than this. The clover alone is unable to accomplish this result; the germ alone is not prepared to thrive luxuriantly, but if the two meet, together are they able to accomplish what no other cultivated crop plant can do.

The explanation of why the clover is able to forego nitrogenous fertilizers is thus made. The mystery which has enveloped this common plant has thus been cleared up. Does it not enhance our interest in it all the more? For, indeed, such a discovery as this opens up possibilities that could scarcely have been dreamed of before such a process had become thoroughly known.

While this characteristic of fixing the elemental nitrogen of the air is shared by some other organisms than the clovers, it is within the limits of this family that we find it possible to utilize this property. Peas, beans and vetches, as well as the clovers, possess this peculiarity. In general it is confined to the legume family, but a few species of plants outside of this genus also have a similar property, although in these cases no practical value inures. Probably some of the lower algae, and also some species of bacteria, independently possess a similar power, but it remains so far the peculiar province of the legumes to function as nitrogen collectors in a practical way.

The Cost of a Ration. Mr. Phelps Figures.

ED. HOARD'S DAIRYMAN:—In your issue of June 30th, I find my name mentioned several times in connection with a communication from the pen of C. W. Jennings, quoting from a statement made by Mr. J. W. Ingram, which, to say the least, is misleading, and why any man should write such misstatements, without first finding out the truthfulness of the statement, purporting to come from me, is an enigma; especially a writer for agricultural papers to be read by the public.

I scarcely ever write for the press. I am more content to read of others doings, and practicing the best information I can obtain, to build up and solve the economic questions in dairying. I flatter myself that I have been somewhat successful, yet I believe that what I don't know, to be demonstrated in the future in comparison to what I do know, would fill volumes.

I have traveled over the state and have attended many farmers' institutes, as a speaker, and one of my hobbies has been "economy in cattle foods," as I consider that one of vital importance to the dairyman.

Now in regard to the statement I did make: At the Pennsylvania State Dairyman's Association, held at Corry, February, '98, in speaking on the subject, Enonomy in Cattle Foods, I gave my experience in my own dairy, not to boast, but to show the dairymen that what one man could do, others could do. I write this from a memorandum written that year. The ration I was giving our cows was this:

Cotton seed meal, 2¼ lbs. at $18.00 per ton..	$.02
Bran, 2 lbs. at $12.00 per ton.....	.012
Ensilage well cured, 30 lbs. $1.66 per ton...	.025
Hay good clover, 20 lbs. $5.00 per ton.....	.05
Cost of ration per cow.....	$.107

I reckon three tons ensilage equivalent to a ton of hay. Allow me to state our dairy is a winter one, cows becoming fresh in the fall. Now the result: Twenty-three cows gave twenty-six pounds butter per day at a cost, for feed, of 9½ cents per pound. Butter made in one pound prints, and churned each day. Sold for from 18 to 25 cents at the railroad station, and sold to the grocery trade; not a very great price, but as neighbors about me were selling their butter, at the same time for from 12 to 14 cents, costing them for feed 18 to 20 cents a pound, I thought our work was encouraging. Would have fed more ensilage and less hay, but corn was short that year.

Now I will give our report of our doings the past winter. Our ration consisted of:

50 lbs. ensilage well eared, $1.66 per ton.....	$.04
7 lbs. hay at $5.00 per ton.....	.014
5 lbs. cotton seed meal, $18.00 per ton.....	.045
Cost of ration per cow.....	$.099

Twenty-six cows, including five two-year-old heifers and one farrow cow, made thirty-two pounds of butter per day, at a cost for feed alone, of eight cents per pound, made in the same form as the year previous, sold a little higher in price.

For the benefit of Mr. Jennings and all inquiring friends, I will say that we sold seven old cows, that I did not want any longer, for beef; could have sold all of them for the same purpose, and I can assure all concerned, that our cow's "bones never sigh for pastures they know not of."

As for Mr. H. C. Crawford's case, I know nothing of. Am well acquainted with him, and can assure the public his word is as good as his bond. It is more than likely that the whole business is tarred with the same stick. My cotton seed meal ration is large, but I found it to be adulterated with hulls, had to increase it. J. B. PHELPS.

Crawford Co., Pa.

MILKMEN who assume that formaldehyde cannot be found by the chemist, should "watch out." A Kansas milkman has found out that the chemist can find it and he paid $1,000 in fines in consequence. It would have paid him better to have had a little sour milk left on his hands.

CONCERNING OUR ADVERTISERS.

"FARMERS who have never used a low down Handy Wagon do not know that a large per cent of the labor on the farm is useless, as it can be saved by using labor saving tools. The Handy Wagon ranks first as a labor saver.

"The Havana Metal Wheel Co., of Havana, Ill., are making a specialty of low down Handy Wagons, made of both steel, and steel and wood. Also steel wheels for ordinary farm wagons made to fit any skein. This class of wheels does not rot or dry out and lose the tires, but the wheels are always ready for use. Write them.

BINDER TWINE HISTORY.

The single strand binder twine, in general use to-day, was the original conception of Mr. William Deering, of the Deering Harvester Co., Chicago. The value of the idea is apparent, since without it the modern twine binder would be impossible. The Deering Harvester Company is the largest manufacturer of binder twine in the world.

THE T. M. Roberts Supply Co., Minneapolis, Minn., offer bargains in almost everything that is bought and sold for household or farm use, comfort or luxury. They advertise bargains this week in Binder Twine. One can save money, and much of it sometimes, by watching these bargains offered by enterprising firms.

THE Edgewood Refining Co., of Cleveland, O., are advertising their Diamond Anti-Fly preparation. The users of this preparation speak very confidently as to its merits. They send samples sufficient for trial for very small consideration. See the ad.

THE Genesee Salt Co. advertisement mentions the fact that users of their salt have captured the sweepstakes premium at National Creamery Association for five consecutive years, a record they may well feel proud of. As well is it a record that ought to interest buttermakers everywhere. In these days of sharp competition there is economy only in the use of the very best methods and the profit lies mainly in quality. Read the ad. and write F. A. Tripp, No. 34 Clark St., Chicago, Ill., western representative of Genesee Salt Co., for entry blanks in their 1899 Educational Contest for creamerymen.

THE American Well Works, of Aurora, Ills., are putting on the market a Well Drilling Machine, with gasoline engine mounted on same trucks. This is particularly desirable, as it is their well known "Elliptical" driller, which handles equally well cable rock tools, or hydraulic and jetting tools. Description and illustration can be had by writing them.

CONCERNING Shoo-Fly, advertised before the DAIRYMAN readers, "Buff Jersey," well known to all, has following to say:

"Brother dairymen, be humane and protect your cows from flies. It will pay you a hundred fold in dollars and cents. I have used "Shoo-Fly," made by the Shoo-Fly Mfg. Co., 1005 Fairmount Ave., Philadelphia, Pa., several years, in different states. It has always proven effectual and profitable. In September, 1898, I exhausted my supply and concluded to do without for balance of season. My cows expressed their indignation by cutting off the flow of milk to such an extent, I hastened to order another ten gallons. This June, (1899). I ordered twenty gallons for my herd. It pays." BUFF JERSEY.

COMBINATION BULLS FOR OREGON AND PENNSYLVANIA.

Mr. L. T. Birchard, Birchardville, Pa., has placed a combination bull at the head of his herd. He selects Brown Bessie's Diplomatist 52090, grandson of Brown Bessie, champion butter cow at the World's Fair, and Diploma, sire of 49 in the list, including Merry Maiden. The reputation of Combination 4389, the sire of Diploma and 25 daughters with records, is wide. It was not only that he was the grandsire of Brown Bessie and Merry Maiden, the unapproachable cows in the great World's Fair tests, Brown Bessie making more butter than any cow in the test and gave more milk than any Jersey, and Merry Maiden being the champion of all breeds in the three tests combined; these facts in themselves establish the reputation of Combination as a foundation unassilable. Mr. Birchard owns a splendid herd, and young Diplomatist will have ample opportunity to extend the reputation of the Combinations in the Keystone state.

Mr. G. B. Miller, Gervais, Oregon, has been casting about for a first class Combination bull, and settled upon Diploma's Mariner 53544, a grandson and great grandson of Diploma. His dam Marine 53459 has a record of 16 pounds, 8 ounces made a long time after passing her prime, and her grand dam has a record of 14 pounds, 8 ounces. Both were dairy cows in every sense of the word, the type of cows that Mr. Miller wishes to duplicate.

The demand for the blood of Diploma increases as the list of his tested daughters and grand daughters increase. Diploma left behind him 85 daughters, and the fact he has 49 tested daughters proclaims the prepotency of his great sire Combination, and when it is stated that in addition to his 49 tested daughters, Diploma has 14 sons with tested daughters, it places him above his sire and demonstrates that he not only inherits his prepotency, but he is handing it down in every line and through every channel. H. C. TAYLOR, Orfordville, Wis.

THE Jersey Bull by Pedro Signal Landseer out of Lois Emerson, recently advertised in this paper by Hood Farm, Lowell, Mass., has been sold to C. T. Rossiter, of Claremont, N. H. He is a very fine bull and gives a great promise of developing into a show animal. His sire and dam are both prize winners. Lois Emerson is one of the deepest and most persistent milkers in the Hood Farm herd. She has given for the last five months 6,000 pounds of milk, and she will make a large yearly milk and butter test. Hood Farm has also recently sold to E. E. Day, of Weeping Water, Neb., a bull carrying a large per cent of the blood of the great winners in the World's Fair tests. He is by Brown Bessie's son and out of Islip Lenox, the cow that stood seventh in the ninety days test at Chicago.

HOLSTEIN CATTLE! The Choicest Milk and Butter Breed in the World. Write to Wis. Live Stock Ass'n, Appleton, Wis., U.S.A.

SHADY NOOK HERD Holstein-Friesians Choice Chester-White Pigs 2 to 3 months old, both sexes, for sale. W. R. GATES, Ripley, Jefferson Co., Wis.

Registered Holstein-Friesian Cattle. Best families of the breed. Aaggies, Waynes, De Kols, Netherlands, Pauline Pauls, Pietertjes. WM. O. JACKSON & SONS, South Bend, Ind.

HOLSTEIN-FRIESIAN CATTLE
Owned by JONES & RANDALL, Hustisford, Wis. 100 head to select from. From families rich in butter fat. Herd now headed by Barron Paulina De Kol. Stock for sale. Prices reasonable.

HOME FARM HERD.
Headed by Jewel of Home Farm, Sweepstakes Holstein-Friesian Bull Trans-Mississippi Exposition Omaha, Neb. Seventy-five head to select from. W. B. BARNEY & CO., Hampton, Iowa.

MEADOW LAWN HERD Holstein-Friesians.
Herd headed by Sir Brookside De Kol. Choice young stock for sale. Come and see them. C. W. HARRISON, Ringwood, McHenry Co., Ill.

HOLSTEIN-FRIESIAN BULL CALVES From advanced registery and officially tested, prize-winning dams, as high as the 21-lb. class, 70 to 76 lbs. milk from cows. Quality as well as quantity. If you want *the* best address MALCOLM H. GARDNER, Darien, Wis.

OAK GROVE HERD H-F. Cattle.
Cows, Heifers and Bull Calves For Sale.
C. H. Stevens, Jefferson, Wis.

Holstein-Friesians
MECHTHILDE BULLS FOR SALE. Address M. W. BARDEN, Portage, Wis.

McGEOCH FARM Holstein-Friesians.
Herd headed by Gem Pietertje Hengerveld Paul De Kol and Johanna Paul Colantha. A few young bulls, 3 to 7 months old for sale at bargain prices. H. B. DAGGET, Mgr., Lake Mills, Wis

130 Holsteins. First prize herd at Trans-Mississippi Exposition at Omaha. 1st and 2nd on aged cows and 1st. on two-year-old heifer in the seven day butter test, open to all breeds at same Exposition. Three cows in this herd have produced the most butter in seven days of any cows ever officially tested. A score of others nearly as good. Our richest bred bull calves are taken young. Sons of De Kol 2d and Netherland Hengerveld head the herd. Animals of both sex and any age for sale. Write stating just what you want. HENRY STEVENS & SONS, Lacona, Oswego Co., N. Y.

MECHTCH'LDE
The greatest butter cow in Holstein history is owned, with her son and two daughters, at **Valley Mead Farm.** Mechtchilde's butter record is the largest in the world, 30 lbs. 10½ oz. from 717 lbs. milk in seven days. Breeders Gazette says: "**Mechtchilde** was one of the 'wonders' of the breed." Men who are interested in phenomenal cows are invited to come and see the greatest butter, milk and prize winning cow that ever existed in America, and that sold for the largest price ever paid, $2 500. **Valley Mead Farm Monticello, Green Co., Wis.**

Markham Manor Farms. Simonsville P. O. Andover, Vt.
Holstein-Friesian cattle bred from the most fashionable butter families, individually large producers, and of the most approved show form. The herd contains seven daughters of Sir Netherland Soldene Clothilde, No. 18390, H. F. H. B., the most remarkable show bull of recent years. Also large English Berkshire Swine from noted prize winning and imported stock. Write for description and prices to J. A. THORNTON, Mgr., Simonsville, Vt.

GUERNSEYS AND POLAND-CHINAS.
Best from the most noted prize-winners. Calves and Pigs at bargain prices. CLAYTON C. TAYLOR, Lawton Station, Erie Co., N. Y.

GUERNSEYS FOR SALE. The increase of my herd is a few young things of both sexes, from one to eighteen months old. Prices corresponding to age and quality. F. W. TRATT, Whitewater, Wis.

FAIRVIEW FARM GUERNSEYS.
FOR SALE—Yearling Bull, BEAUTY'S KING 5301. Sire, King of Kenosha 3706, Dam, Kenosha Beauty 5293. Grandson of Benjamin and Squire 4th. Also younger bull calves of good breeding. Address C. W. WILCOX, Des Moines, Ia.

GUERNSEY Cattle—SHETLAND PONIES—Old Homestead Herd was Champion at O., Ill. and In. State Fairs, 1898, winning against well-known O., Pa., and N. J. Guernsey show herds. Over twice as much prize money as all competitors combined at above fairs No better collection in America.
Breeding Stock for Sale. Inspection invited.
L. V. AXTELL, Perry, Lake Co., O.

Riverside Guernseys, CHAMPION Herd
AT NEW YORK STATE FAIR,
1898, in competition with the leading herds of the country, won eight firsts and sweepstakes. Young stock by COMUS, sire of most of the winners, for sale. FORSYTH, Riverside Farm, Owego, Tioga Co., N. Y.

ROSENDALE GUERNSEYS
Our herd has won first prize at the Wisconsin State Fair every year since 1894, and also won first at Minnesota State Fair and at the Trans-Mississippi Exposition in 1898. We keep only 400-lb. cows. Tuberculin tested.
GEO. C. HILL & SON, Rosendale, Wis.

"Florham" Guernseys.
First Prize Herd wherever shown, viz: New York State Fair, 1895 and 1897; Bay State Fair, 1895; Inter-State Fair, Trenton, N. J., 1895 and 1897; Madison Square Garden, 1895; New Jersey State Fair, 1897. J. L. HOPE, Farm Supt., Madison, N. J.

GUERNSEYS!
84 Cows averaged 399 lbs. of Butter each in 1898. . .
Some Choice Young Stock For Sale.
ELLERSLIE STOCK FARM, Rhinecliff, N. Y.

AYRSHIRES Finely Bred and from the very best families. Stock for sale, bred for milk and butter qualities. Also fine herd Chester White Swine. Correspondence solicited.
FRED TSCHUDY & SON, Monroe, Wis.

[Second Paper.]

Delaware Co., N. Y., Dairy Association.

ED. HOARD'S DAIRYMAN:—Afternoon Session.—The program was now resumed, and R. P. McIntosh, of Delhi, N. Y., read a paper on "How to Conduct Agricultural Exhibitions." Mr. McIntosh reviewed the history of the fairs held in Delaware County. Some of these fairs were very successful, and the plan of conducting them was described.

The purely agricultural fairs had given the best satisfaction to the majority of the people. At these fairs exhibitors used their opportunities, and the exhibits were large. The attractions were, good music and an address. The farmers in the vicinity took an unselfish interest in the fair. The greater part of the premiums were given to farm animals, and not to trotting horses. The admission on the grounds of the vulgar sideshow and fakir have been causes of the decline of our fairs. The managers sacrifice principle for temporary gain.

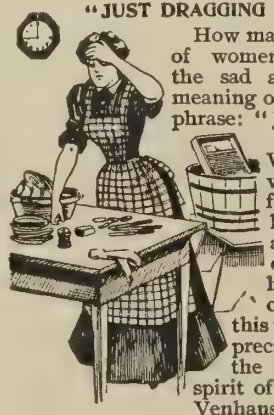
Mr. C. O. Potter, of Leonta, N. Y., followed with a paper on "Breeding the Dairy Cow." He said:"Choose the breed you like the best, that will the best serve your purpose. Begin by buying the best sire you can get of that breed. We hardly appreciate the value of the well-bred sire, for he may have concentrated in his blood the characteristics of several generations of the best dairy type of cows. We can generally depend on the laws of heredity to transmit these qualities from the sire to the offspring, although there are occassionally variations from an established type. The type of the cow will be changed by a change of environment. Breed constitution and individuality in your stock."

Mr. George Grant, of Delhi, N. Y., read an excellent paper on "Making Farming a Success under Present Conditions." The following is an abstract of the paper: "This is the time of close competition and small profits, and many farmers are discontented and dissatisfied with their business. Yet, with good management, I believe we can still make a good living on the farms. I will mention what I believe to be some of the reasons why farmers do not succeed. I believe that failures are more often made on large farms. One hundred acres are usually enough for one man to farm successfully. I would divide such a farm as follows: 15 acres of woodland, one half the remainder for tillable land, and the other half for pasture. Such a farm should be made to keep thirty cows. The most of the work on a farm of this size could often be done by the man and his family, and save the expense of hired help. On the small farm the work would be much better done, more stock kept to the acre and therefore more manure would be used per acre.

The foundation of all successful farming is the saving and the right use of the manure. I would as soon have a leak in the bottom of my grain bin, as in the manure gutter. The farmer should be continually working to increase the quantity, and improve the quality of his manure, and he will obtain the best results, if it is applied to the land as fast as made. As to the commercial fertilizers, my advice is to go slow. If I had $40 to spend for commercial fertilizers, I would take half of it and hire a man to draw leaves, muck and other material and make a compost heap.

While I would not advocate economy that amounts to penuriousness, yet with the small profits in farming, there is but little money to spend for luxuries, and especially the farmer who is in debt, should be very careful about spending money for what he does not need. The farmer with good habits has a much better prospect for success.

I am sorry that some farmers have habits that are not only expensive, but injure the health. I refer to the use of liquor and tobacco. The farmer who has the liquor habit is almost certain of financial failure. I can hardly say too much against the tobacco habit. The weed is so distasteful to animals, that none will touch it, and the only good use for it, is to destroy insects on animals and plants. Ten cents a day spent for cigars, if the interest was compounded for every year, for forty years, would amount to $6,000, which is sufficient to buy a good farm of one hundred acres. Surely, the habits take more money from the farmers, than does the tax collector. Many farmers do not succeed for lack of energy, or, in plainer words, laziness. Hard and well directed work is the price of success."



Mrs. R. E. Haddow read an essay entitled "The Man Behind the Plow." The essay was full of good thoughts, well expressed, and delivered.

Wm. Hymers, of Delaney, N. Y., spoke on "Supplemental Feed for the Dairy". The following are some of the good points in his address: Don't buy feed for your cows, grow it on the farm. Commence in the fall before the next season, and sow rye. Sow about one-half an acre for twenty cows. Don't turn the cows on the pasture too early in the spring, but commence to cut the rye when it is about one foot high. Feed this until the first of June. As you will have full feed for your cows in the pasture through June, you will not need to feed the cows this month. Plan to have oats and peas to feed when the pastures become short. Sow oats and peas at different times, and don't be afraid to sow too many, for if you don't feed them green, they make good hay, or you can let the oats and peas get ripe, and thresh and grind them.

After the peas comes the corn. I don't think dairy farming can be made profitable here without corn. We must depend on the silo for cheap food for the cows. You ask how are we going to get the manure to grow these crops? I answer you must save all the manure, and keep all the stock you can to make manure. Make the gutters tight, and use absorbents. The best absorbent is cut straw. After you have made and saved all the manure you can, if you still lack manure for the soiling crops, use some commercial fertilizers.

Mr. Walter Gladstone next talked about "The Best Education for Farmer's Sons and Daughters." He first spoke about the laws of heredity, and said the child is the result of the life of the several generations of his ancestors. If I were to educate a child, I would want one well bred. First in importance is the home education. If this is good, it will do more toward starting the child right than anything else. First give a child a general education, and then technical education. Teach them some useful avocation.

"JUST DRAGGING AROUND."

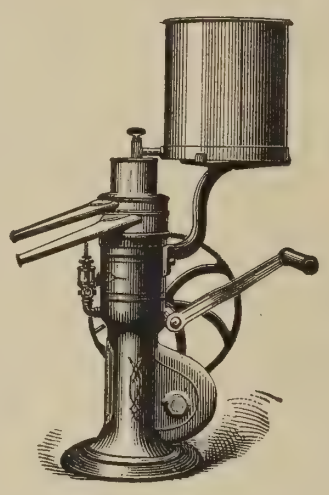
How many thousands of women understand the sad and pitiful meaning of that simple phrase: "Just dragging around." Women everywhere who feel that they have a work and a mission of womanhood to accomplish in this world will appreciate instantly the disheartened spirit of Mrs. Mattie Venhaus, of Tioga, Hancock County, Illinois.

"I had been sick for seven years," she says; "not in bed, but just dragging myself around. At last I took three bottles of Dr. Pierce's Favorite Prescription and five of 'Golden Medical Discovery,' and it is *impossible to describe in words* the good these medicines did me. My husband says 'Golden Medical Discovery' is the best medicine he ever tried for a cough. No praise is too high for Dr. Pierce's medicines."

Another lady, Mrs. R. P. Monfort, of Lebanon, Warren Co., Ohio, says, "I think Dr. Pierce's Golden Medical Discovery the finest medicine on record. I have taken a number of bottles and it is the only medicine that relieved my terrible headaches."

Women who suffer should write to Dr. R. V. Pierce, of Buffalo, N. Y. He will send them the best professional advice that can be had anywhere in America and entirely without charge. Neither the "Golden Medical Discovery" nor the "Favorite Prescription" contains any alcohol to inebriate or create a morbid craving for stimulants.

Every woman should own a copy of his splendid book "The Common Sense Medical Adviser." It is the grandest medical book for popular reading ever written. It contains a fund of knowledge of precious value to women. It has over a thousand-pages elaborately illustrated with engravings and colored plates. The first great edition of more than half-a-million copies was sold at $1.50 each. The profit from this induced Dr. Pierce to carry out his cherished intention of issuing a free edition one copy of which in paper-covers will be sent for the *bare cost of mailing*, 21 one-cent stamps, or a heavier cloth-bound copy for 31 stamps.



The One Successful Color

IT gives entire satisfaction and is the only color that buttermakers should use. It is the one color found in over ninety per cent of the creameries of the country. Butter containing Wells, Richardson & Co.'s Color has the highest standing in the markets. . . .

Teach them to be good citizens. Teach them to depend on self.

In the absence of Mr. J. B. Mable, whose name was on the program to talk about the "Silo and Ensilage," the subject was taken by Mr. R. Garrison. In his experience, the best ensilage corn was grown by planting in rows three feet apart in drills, and thinning the plants to six inches apart. "The stalks on my ground have grown 16 feet high, and will make twenty tons of ensilage per acre. Five tons will winter a cow. I can put the corn in the silo, when it is grown, for forty cents per ton. This is cheaper than I have been able to put in my hay. Nothing is added to the corn by putting it in the silo, but the process of fermentation makes it more digestible.

Good ensilage never makes poor milk. In every instance where poor milk has come from ensilage fed cows, the quality of the ensilage has been found poor. Changing the ensilage ration to first-class hay in my dairy has always resulted in loss.

Ensilage well put up will keep two years or more, and one need not fear getting too much, as it may be needed to carry the cows through a drouth in the summer."

The program was concluded by an address by J. W. Mc Arthur, of Bloomville, N. Y., on "Diversified Farming". Mr. McArthur did not advocate, as a rule, diversified farming. He thought the farmers who have adhered the most closely to the cows, have made the most money. Raising colts and keeping sheep, and poultry in connection with the dairy has not paid me. To what extent diversified farming is profitable, will depend on the condition of the farm and the near by market. If one has a taste for them, under the right conditions, truck and poultry farming, in connection with the dairy may be made profitable. W. J.

Delaware Co., N. Y.

Cream Not Churning.

ED. HOARD'S DAIRYMAN:—I have lately had what, to me, is a novel experience. Have been making about fifteen pounds of butter, at a churning for some time; suddenly the butter fell back as much, almost, as half, though the cows are in fine pastures. I couldn't find anything wrong—skim milk had no cream on it; butter apparently all came out of the milk. After some time it was suggested to me that I churn the buttermilk. I did so, though I had never done such a thing in my life—and the result was one to two pounds of butter, though not as much as I had been getting. Today it yields, apparently, as it did before, and I got no butter from the buttermilk.

Bedford Co., Va. MRS. A. W. SCOTT.

The cause of such partial churning can usually be found in the cream, and is of bacterial origin.

The exact cause in this case is, of course, impossible to state, and the most we can do is to make some general suggestions as to the cause and its remedy.

The fact that part of the cream churns out first, would lead us to suspect a difference in the degree of ripeness in different parts of the cream.

If the churning is of the cream from several batches of milk, it is extremely likely, in this hot weather, that there is a decided difference in the degree of ripeness of the different batches of cream. This would not appear when it is mixed, but would show very decidedly in the churn; the ripest cream churning first, and the sweet only separating on rechurning.

Temperature may also have an effect, if your herd is composed of fresh cows and strippers. The cream from the fresh cows will churn at a lower temperature and in less time than cream from cows advanced in lactation.

The kind of ferment present in the cream would also affect the churning; sometimes preventing entirely the formation of butter, at other times allowing partial churning.

The above are merely suggestions as to what may cause the result given in the letter, and the only way to remedy the trouble is to watch carefully the ripening and temperature of the cream, and note how the churn follows.

How Renovated Butter is Made in One of the Factories.

The subject, renovated butter, has occupied considerable space in the dairy press of late, but nothing has been said about the manufacture of same; and thinking it may be of some interest to the readers of the *Reporter*, I will tell them what I saw in one of the so-called manufacturing establishments. It must be understood that no one, not connected with the concern, was allowed admission, but, being armed with the necessary credentials, (a search warrant), we were not refused admission to this sceret den where loud butter was hushed, and green, white and gray butter made yellow, sour butter made sweet, and in fact, everything that was not butter was turned into butter.

The first floor had the appearance of an ordinary butter store or commission house. A long-whiskered man in charge was asked to lead the way, which he did, after some hesitation. A door leading into a dark hall was opened, and immediately behind it was another leading to the cellar. There was only room enough for one man at a time, and the first door had to be closed before the second could be opened, leaving one in perfect darkness; a long, narrow, dark stairway led to the basement. After reaching the bottom no one can imagine what first drew our attention. With a dim light of a kerosene lamp we commenced the search and found what renovated butter was made from; butter and butters, white butter, green butter, brown butter, soft butter, butter old enough to talk loud, butter old enough to walk, butter in jars, boxes, tubs, tins, cans and barrels.

A door was discovered, pushed open, and we were in the work room where the secret process was carried on. A large wooden tank about five feet in diameter and six feet high, was in one corner. A trap door from the floor above was discovered, which probably was used in filling the tank from above. Steps leading up to the tank were climbed, after slipping back two or three times on account of the grease on them, and there is where the melting or renovating was going on. This was heated with a set of steam pipes leading from a boiler in another corner. From the tank the oil was drawn off and cooled in another set of tanks, and from there it was put into a churn and churned in buttermilk, washed, colored, salted and worked, then packed into tubs and put upon the market and sold for what it would bring.

Before the renovated act went into effect, the public was deceived by the manufacturer putting this stuff into pound prints and giving it some fancy name; but since people have found out what renovated butter is, it has almost entirely disappeared from the market.

The claim is made by some that it is the poor man's butter, and that it is butter made from what may be termed by-product, and it is a step forward; it is using poor dairy butter and putting it into a marketable article. All of which looks good on paper, but is not true, because the public was charged within one cent per pound of what creamery butter was being sold for, and in most cases it was sold for creamery butter and since the required labeling has revealed its character no one wants to buy it, and all that has been necessary is to inform the public what it was.

During the past winter it has been a greater enemy to the dairymen of Minnesota than oleomargarine.—B. D. WHITE in *Dairy Reporter*.

NO PRESERVATIVES IN MICHIGAN.

The following law was passed at the late session of the Michigan legislature, and Gov. Pingre has signed the same. There are only two sections. The first reads as follows:

"Section 1. No person shall offer or expose for sale, sell, exchange or deliver, or have in his possession with intent to sell exchange or deliver any milk to which water, chemicals or preservatives or any foreign substance, has been added. The term milk, as used in this act, shall include all skimmed milk, buttermilk, cream and milk in its natural state, as drawn from the cow."

The second section says:

"Who ever shall do any of the acts or things prohibited, or neglects or refuses to do any of the acts or things enjoined by this act, or in any way violates any of its provisions, shall be deemed guilty of a misdemeanor, and shall be punished by a fine of not less than one dollar nor more than one hundred dollars and the costs of prosecution, or by imprisonment in the county jail not more than ninety days, or by both such fine and imprisonment, in the discretion of the court."

The JERSEY MILK CAN

A Strong, Well Shaped and Well Finished Milk Can at a low price.

This can has our "Victor" Can Breast, is perfectly shaped, will not leak, and has no crevices inside where milk can lodge and sour and smell. Capacity five, eight or ten gallons.

THE MILK CAN TRADE MARK IS ON EVERY CAN.

If your dealer has not got them, we will ship on receipt of your order. Write for our Handbook No. 32, "A Study in Milk Cans."

Cheese Bacteriology.

In his report of practical application of bacteriology to European dairying, published in the eleventh annual report of Storrs (Ct.) Experiment station, Prof. H. W. Conn makes the following observations in regard to the development of bacteriology in connection with cheese making in Europe:

"During the last few years a considerable majority of the students of dairy bacteriology have turned their attention from the study of milk and butter to the study of cheese. The reason for this is a practical one. It has been recognized for some time that the character of the different varieties of cheese is due, at least in considerable degree, to the peculiar kinds of fermentation which take place in the cheese during the ripening. In the cheese which are popular in the markets of Europe, the variety of flavor is very great. One who goes through the markets in the different countries of the Continent is especially struck with the extremely great differences between the different kinds of cheese, and the great number of varieties which are popular in different localities. If these differences are due to types of fermentation it would be plainly a matter of great practical value to dairying if there could be discovered some strictly scientific method of producing the different varieties. The bacteriologist who shall discover the means of applying, in a practical way, to cheese making, the facts which have been discovered in connection with bacteriology will not only gain a great reputation for himself, but will undoubtedly reap a large amount of financial profit at the same time.

The problems connected with cheese offer, therefore, a very fertile field for research. In the application of bacteriology to butter making, it has been thought that perhaps no further great improvement can be made now that we have actually learned to control the flavor of butter, at least to a considerable degree, by the use of pure cultures. But in the operation of cheese making, there are almost limitless possibilities, because of the many varieties which each country demands. If it were possible to find some means of making the popular cheese in other localities than those where they are ordinarily made, it is plain that a great impetus could be given to dairying. If Edam cheese could be manufactured equally well in all countries, where they are in demand, if Swiss cheese could be made with equal ease and equal surety outside of Switzerland, it is of course plain that the whole condition of the dairy industry would be changed. For these various reasons it is that in the last few years bacteriologists have ceased to pay much attention to the problem of the relation of bacteria to butter, and have given a correspondingly great amount of study to the problem of cheese making.

The problem, however, has proved to be an extremely difficult one. Its very complexity has made the subject very difficult to reach. There is no question that the flavor of the cheese is developed during the period of ripening, which occurs after the cheese is made. But in that ripening there are a variety of changes that take place. The changes in the chemical nature of the cheese are very profound, and while these are, in part, due to bacteria they are apparently also in part due to certain unorganized ferments which are present in the milk. Moreover, the growth of bacteria in such cheese is irregular and presents problems which have hitherto been largely insoluble. That the cheese flavor is due to bacteria or to moulds is everywhere agreed.

Bacteriologists are as yet unable to agree as to what kind of bacteria are most intimately concerned in the ripening process. While there are some who bring forward an abundance of evidence that the lactic organisms are those primarily concerned in the process of cheese ripening, there are others who bring forward a large amount of good evidence that it is not the lactic organisms, but rather bacteria, which give rise to an alkaline reaction and which have power to digest proteids; while beyond doubt some types of cheese owe their peculiar character to molds, rather than bacteria. It is, of course, clear that when such a simple, primary matter as this cannot be settled with any degree of unanimity, we cannot expect to find any very considerable amount of practical results arising from bacteriological work. Until a more thorough knowledge of the whole process is obtained we can expect to find very few practical applications of bacteriology in cheese making.

At the same time, there have been some improvements which have taken place in cheese manufacture as the result of bacteriological knowledge. It has been shown beyond peradventure that a majority of the "faults" which arise in cheese, and which make their appearance during ripening, are due to the growth in the cheese of certain malign kinds of bacteria, or sometimes due to the undue growth of bacteria, which, under different conditions, would produce no injurious effect. The "faults" which arise in the cheese during ripening are quite varied and need not be enumerated. They concern the appearance, the consistency, the taste, the odor, and the healthfulness of the cheese, and while it would be premature to say they are all due to improper fermentations, it is now known beyond question that at least a majority of them may be attributed to such causes. Moreover, it is known that in many cases the sources of such troublesome fermentations lie in the fact that there has been used in the manufacture of the cheese, milk which has become unduly contaminated with malign bacteria. There have been enough instances discovered where a troublesome "fault" in the cheese has been traced to the milk from a single dairy to indicate that in the successful method of cheese making of the future it will be necessary to have a more careful control over the kinds of milk used in the manufacture of cheese.

It has been suggested that perhaps it may be necessary to use the same process of pasteurization for the purpose of getting rid of such possible errors as is used in the butter manufactories. The pasteurization of the milk for cheese making has as yet, however, not been applied in any cheese factory. A few experiments have been made by bacteriologists to determine whether it is possible to pasteurize the milk without injury to its curdling powers under the influence of rennet. Of course, if such were not the fact, it would follow that pasteurization could never be used with success in cheese making. These tentative experiments have indicated that when the time comes that bacteriologists can offer promise of a great surety in the results, pasteurization of the milk for cheese making is perfectly feasible, for when it is properly conducted the milk will be curdled by the rennet in a perfectly normal fashion.

Almost the only practical application of bacteriology in general cheese making which has been introduced as yet, has been in the development and the application of a so-called "fermentation test" designed for the purpose of enabling the cheese maker to exclude from his cheese any milk which is likely to produce trouble. Its application is extremely simple, and there have already been devised and put upon the market forms of apparatus which make it convenient to use in ordinary cheese factories. It consists simply in testing separately samples of milk from each patron. The essence of the process is merely this:

A small sample of the ordinary milk is put in a special vessel by itself, and is then subjected to a moderately warm temperature and carefully watched. If the milk is found to curdle in a proper time in a normal fashion, it is regarded as perfectly safe to use; but if the milk becomes full of gas bubbles in the curdling, if the nose or the tongue detects any specially unpleasant or unusual qualities, it is inferred that the milk is filled with bacteria that will be deleterious to the process of cheese making. When this occurs, the milk from the sources from which the sample is taken is not allowed to be mixed with the ordinary milk for the purpose of making the cheese. This fermentation test is not used very widely. As a rule, cheese is made today practically as it was fifteen years ago, before any knowledge of bacteriology was obtained. But cheese makers have learned that this fermentation test may be used at times of trouble, and may be used as a means of discriminating milk that can be safely put into cheese from that which is not safe to use in this way. The practical difficulty in the way of the test is, of course, that the cheese maker may not discover until weeks after the cheese are made that they are likely to develop certain undesirable faults, and by this time the fermentation test is of comparatively little use. The original source of error has very likely disappeared, and the application of the fermentation test after the discovery that the cheese are liable to "faults" is too late to be of much use. Nevertheless, the fermentation test has been in some cases found to be of practical value.

The success of the use of pure cultures in improving the quality of butter, and the manifestly close relation between the form of fermentation in ripening cheese, and the character of the cheese, suggests, of course, a very great possibility of the application of pure cultures to the process of cheese making. If it is true that the flavors of different kinds of cheese are due to different species of bacteria or moulds, it ought to be possible to use pure cultures of the proper species in such a way as to give rise to perfect uniformity in the results, and to make it possible to produce, in any part of the globe, any particular kind of cheese. It is along this line that bacteriologists are working today, hoping that by an extension of their experiments they will learn what kind of pure cultures can be used in cheese making to give the most desirable results. Up to the present time, however, no practical results in this line of work have been reached. There is, it is true, one European bacteriologist who has put upon the market a pure culture of bacteria for cheese making, making great claims for it, as giving rise to a very high grade of cheese with uniform results. It has not been as yet used to any very great extent, and, certainly, has as yet no very great reputation. There is another who has succeeded in making fine cheese by the use of certain species of mold. Beyond this, while other bacteriologists have species of bacteria which in their laboratory experiments have produced very desirable results, and have given rise to cheese with flavors that appear to be normal and uniform, the application of the method of the artificial use of bacteria in cheese making has scarcely extended beyond laboratory experiments, and in practical cheese making is as yet almost unknown.

Tests of Holstein-Friesian Cows from March 1 to May 1, 1899.

ED. HOARD'S DAIRYMAN:—The following are tests of Holstein-Friesian cows, made by Agricultural Colleges and Experiment Stations from March 1 to May 1, 1899. The butter fat is determined by the Babcock test and the butter calculated on the basis of 80 per cent fat to a pound of butter, the rule established at the World's Columbian Exposition.

Aagie Maxima 6001; age 12 years, 9 months, 29 days; milk, 440.1 pound; butter, 18 pounds, 11.3 ounces.

Fanny Douglas 4th 41943; age 2 years, 11 months, 15 days; milk, 376.7 pounds; butter, 14 pounds, 14.8 ounces.

Belle of Schillaard 3d's Aaggie 36825; age 5 years, 5 days; milk, 377.1 pounds; butter, 16 pounds, 13.5 ounces.

Leah Canpbel 35275; age 5 years, 10 months, 26 days; milk, 368.7 pounds; butter, 15 pounds, 7.2 ounces.

Maplecroft Gem 35909; age 5 years, 5 months, 11 days; milk, 475 pounds; butter, 20 pounds, 1.6 ounce.

Maplecroft Maid 35907; age 5 years, 4 months, 2 days; milk 530 pounds; butter, 22 pounds, 9.3 ounces.

Nieta 2d 36583; age 5 years, 3 months, 22 days; milk, 469.6 pounds; butter, 15 pounds, 10.5 ounces.

Pana 33959; age 6 years, 6 months, 18 days; milk, 539.7 pounds; butter, 19 pounds, 6.6 ounces.

Piebe Queen 29065; age 7 years, 14 days; milk, 342.4 pounds; butter, 15 pounds, 3.1 ounces.

Piebe Queen (second test); milk, 427 pounds; butter, 18 pounds, 12.6 ounces.

Sylva Netherland 44119; age 5 years, 10 months, 29 days; milk, 444.8 pounds; butter, 16 pounds, 4.1 ounces.

Flora Brank 38769; age 4 years, 7 months, 25 days; milk, 467.2 pounds; butter, 17 pounds, 1.6 ounces.

One hundred pounds of cream from Jersey cows' milk gave 52 pounds of butter; the same quantity of cream from Short-horns, gave only 47 pounds; from Ayrshires, only 43 pounds; and from Dutch cows, called, erroneously, in the States, Holsteins, a little over 30 pounds.—*Farmers' Gazette*, Ireland.

Perhaps it did in the individual case above given, but you might turn the list upside down and be just as near the truth. The yield of butter from a hundred pounds of cream depends on the per cent of fat present as well as the other factors which enter into the churning.

Until these data are known, it is absolute nonsense to make any such statement, as the above.

VETERINARY.

Queries in this department answered by Wm. Horne, M. D. V. S., Janesville, Wis.

Cow Physic—Three-fourths to 1¼ pounds Epsom Salts (according to age and size of animals) and two ounces of best ground ginger. Pour over this three pints of boiling water. When at 105° F., give gradually as one dose.

ANTHRAX.

I have a very fine mule that is peculiarly affected. Under the collar, both on the shoulders and on the withers, there have been a series of eruptions similar to boils. That is, small risings would appear, very sore to the touch, the boil would form, and pressure would bring out a core, sometimes leaving a hole an inch deep. The relief would be but temporary, however, as others would form. Please give me a clue to the troubles and how to effect a cure. Since discarding cloth sweat pads and enforcing perfect cleanliness of both neck and leather collar I have not been troubled with galled necks, but the above case is too much for me. Falicon.
Clarksville, Mo.

ANSWER.

You give me positive symptoms of carbuncular anthrax. This is a formidable disease, and needs the best professional skill to be had, and upon the spot. Professional correspondence is out of the question. It is quite impossible to correctly diagnose in all such cases, without a close, studious examination. I would advise you to get the state veterinarian to make such examination, and I sincerely hope you will find me mistaken in my opinion. It may be the result of a scrofulous diathesis, and this is bad enough, but is not so serious as carbuncular anthrax.

BLINDNESS.—RINGBONE.

A few evenings ago the best cow in my herd came in from the pasture blind. Two evenings before that when turning them out to pasture, one of the other cattle hooked her and ran her up against end of barn. Do you think that would have anything to do with it.

I also have a valuable Jersey cow that is lame; something growing on one side of hind foot, that resembles ringbone on a horse.
Wales, Ontario. J. A R.

ANSWER.

First. As a matter of course, any or all such acts are liable to cause much damage. The concussion would be simply of much force, and quite various results might naturally be expected from it. No doubt the concussion caused the affection of the eyes. Keep her alone. Bathe the eyes with strong green tea, cold. To one pint add six grains of sulphate of zinc. Keep dark, but plenty of fresh air; above all, a full, immediate dose of physic and repeat. This will reduce the fever, etc., caused by the shock.

Second. Reduce all the fever, then cut off the hair close and apply Gombault' Caustic Balsam. Keep on until a blister is formed; then cover with hog's lard until all the scabs are off. Then repeat two or three times if needed. No doubt you have an adventitious growth of the bone, ring bone, spavin, etc. Such are the latter.

TESTICLE NOT COME DOWN.

I bought a nice, thoroughbred Jersey bull calf one year ago. The calf was then fifteen days old and is a little over one year now, and but one testicle has come down. The other one comes down a part of the way a little sometimes, but immediately rises.

Will he be all right to keep for raising from, or does this denote a weakness?
Lavonia, Ga. A. N. P.

ANSWER.

I think the bull will come O. K. after awhile. I have known many such, both in cattle and horses, which have come round all right. Doctoring is not needed beyond careful handling, massage of the scrotum. If the scrotum is hard and tense rub with lard oil once a day.

INJURY TO LEG.

I have a cow that has been lame in one of her hind legs for several weeks. I thought at first that she hurt herself in getting up in the stable. She is quite lame when she first gets up or stands in the stable, for some time, but, after walking some little distance, it is scarcely noticeable. She is in good condition, and gives a good mess of milk.
Edgewater, Col. K. Bros.

ANSWER.

I think there is little doubt in your case—no doubt she has, in some way, been injured, and, as a consequence, rheumatism has set in.

Oil of cedar, 2 ounces; tincture of opium, 2 ounces; sulphuric ether, 2 ounces; fish oil 8 ounces. To be well shaken each time before using, and kept tightly corked and out of the sun and light. Rub in hard twice a day, for a while. Give voluntary exercise each day.

SUPPRESSION OF MILK.

I have a fine Jersey cow, had a calf fifteen months ago. Calf was never with cow except for three days. I feed through the winter, wheat bran and clover hay. About five months ago I noticed that two teats were not giving as much milk as usual, and have kept giving less and at the present time I only get one quart of milk from both teats, together, three quarts from another and four and five quarts out of the remaining one. The teats going dry are the two farthest from the milker, front and rear. Subscriber.
Bozeman, Mont.

ANSWER.

There is no accounting for the oft repeated freaks in the giving of milk. Sometimes it will double in quantity quite suddenly, again, the milk will fall off as quickly without apparent cause or notice of any sort. In your case the milker may be the cause. Five months makes the conditions quite chronic and much less amenable to treatment. I believe you had better not attempt doctoring, but wait the issue of next calving. Fifteen months is a long time to milk, though some milk longer. This may be the direct cause.

TUBERCULOSIS.

I have a cow that has been coughing for about three weeks, and breathes very heavy, almost like a horse that has the heaves. When she first took to coughing, she failed in her milk, but gives about as much as ever now. She doesn't seem to be sick at all, eats as much as she ever did, but don't take on flesh; she is very thin now. R. C. R.
Baldwin, Ill.

ANSWER.

I advise immediate removal from the herd. She is a suspicious subject. Still, I, by no means, wish to scare you. Don't use the milk for a while.

Cut off the hair close, under the throat, and apply Gombault's Caustic Balsam, four times a day for a while. Rub in with the back edge of a case knife, for several minutes; after this apply with a thumb sized paint brush. Never again rub at all. When a good scab forms, stop the caustic, and cover with clean, pure hog lard, until the scabs are all off. Then, if needed, only, repeat the same process. On the roots of the tongue place three teaspoonsful of the following: Lobelia, one ounce; gelsium, one dram; water, one ounce, only, cold. Twice a day for four days. Then stop four days, then repeat, if needed, only. Then report, and I hope to have the cough cured; then we are not afraid of a worse condition.

SYMPTOMS OF TUBERCULOSIS.

Please give the symptoms of tuberculosis in cattle. H.
Pine River, Wis.

ANSWER.

It would take quite a large sheet to describe all the symptoms of tuberculosis. In the beginning scarcely any symptoms are manifest. General dullness, lassitude, tenderness of the withers, back and loins, also soreness of the chest. Dry nose, hot horns and ears, changing to cool, and a dry unpliancy of the skin. Usually slight increase of temperature, stiffness of the limbs, changing to first one and then the other. Dry cough, swelling of the joints, etc., etc. Constant desire for the bull, etc. Bone lameness.

TROUBLE WITH BACK.

I have a fine young horse, four years old, affected strangely. He is hearty and in good order and seems to feel well, but there is some trouble with his back. When riding or driving him down hill, he gives away in his back or loins, and sometimes squats almost to the ground. When under the saddle and I mount him, he gives away, and squats very much. He is a very fine horse, a good driver, and I would be glad to cure him. I have had him only a few months, and he was affected as he is now when I got him, so can't tell the cause. W. S. H.
Danville, Va.

ANSWER.

You have a bad case. Use him gently, never ride him, never back him, never overload him. Thus, you may get some usefulness out of the horse.

TO BRING COWS IN HEAT.

Can you tell me what to give, and how to give medicine to bring cows in heat, so as to have them in early spring. I have a few of such cows myself and my patrons are inquiring into the matter also. J. S.
Chippewa Co., Wis.

ANSWER.

All and every form of medicine to bring cows in heat are of a dangerous nature in the hands of the layman, but perfectly safe and effective when prepared by the qualified practical man. See ads. in Dairyman. I can't help you so well in any other way.

PIN WORMS IN HORSE.

What is good for pin worms in a horse? Also what makes the hair come out of the horse's tail, is it the pin worms?
Philadelphia, N. Y. Subscriber.

ANSWER.

Yes, it is the ascarides, i. e., pin worms. Medicines by mouth are of little avail in the getting rid of these parasites. They inhabit the rectum and lumbar region. Injections of cape aloes, one ounce to quart of hot water; when at 100° F. use as injection by a long nozzled syringe. Use carefully, so as not to wound the lining of the rectum. Lard the nozzle before inserting. Use considerable force in pushing in the fluid. Alternate this with fish oil and aloes. In two weeks give a physic to clean out the bowels, etc. A drench of one ounce of cape aloes, two drams of ginger, made into one ball, in two sections, with molasses and give as one dose.

Horse Owners! Use GOMBAULT'S Caustic Balsam

A Safe Speedy and Positive Cure

The Safest, Best BLISTER ever used. Takes the place of all liniments for mild or severe action. Removes Bunches or Blemishes from Horses and Cattle. SUPERSEDES ALL CAUTERY OR FIRING. *Impossible to produce scar or blemish.*

SOUTHERN CLIMATIC FEVER

Same price and same quantity as above.

SAFETY HARD RUBBER MILK TUBES with hole in th end, and DILATING PLUGS

(Patent applied for.)

My Hard Rubber Tubes and Hard Rubber Dilating Plugs supplant all kinds of metal tubes. No blood poisoning or bruising. No dropping out of teat by its own weight. Two hard rubber tubes, 2 and 3 inches long, and two plugs $1.50 the four—and also one bistuary and two plugs $1.50 the three. By mail, the whole set $3.00. In writing for medicine, please say if the cow does or does not come in heat—as the medicines are as different as fire and water.

DR. WM. HORNE, Janesville, Wis.

The Velvet Bean.

[Bulletin U. S. Department of Agriculture.]

The velvet bean is apparently a native of India and has been in cultivation, as an ornamental garden plant, for a good many years It is believed to have been first introduced into this country by the Department of Agriculture, for this purpose, about twenty-five or thirty years ago. In favorable localities it often forms vines 30 to 50 feet in length. It is an excellent plant for quickly covering unsightly objects or arbors. The purple flowers are borne in clusters at intervals of two or three feet at the joint of the stem. These are followed by clusters of short, cylindrical pods, covered with a black, velvety down, which has given the name to the plant. Each pod contains three to six, large, rounded brown and white mottled seeds. The pods are constricted laterally between the seeds, and are often more or less curved.

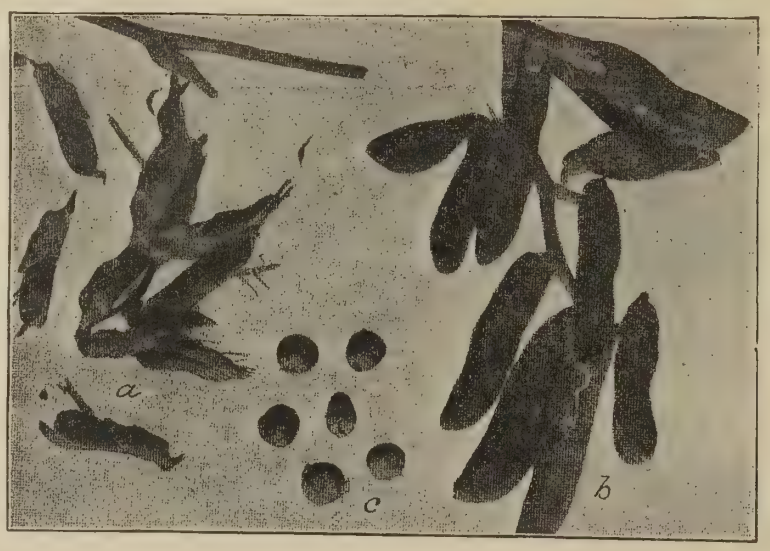
The value of the velvet bean as a forage plant was accidentally discovered about six or eight years ago. Being a native of the tropics it only matures seed in Florida and the lower half of the states immediately along the Gulf coast. It will probably not ripen seed north of a line drawn from Columbia, S. C., 160 or 200 miles back from the coast to San Antonio, Tex. Wherever it ripens seed it is considered to be equal or superior to cow peas, but where seed must each year be purchased it does not equal that crop.

SEEDING.

In Florida, the seed is sown in drills four feet apart, dropping from two to four seeds in hills two feet apart in the row. The seed may be dropped in furrows when the ground is plowed, and covered two or three inches deep. The crop should be cultivated several times. In orange groves and orchards the beans may be sown in drills four or five feet apart, and not less than five feet away from the trees in order to keep the vines out of them.

They make a better mulch crop in the orchard than the cow pea, because when the vines are cut down by frost they form a tangled mass which retains the leaves and protects the soil from rain and sun. The leaves stay on the vines longer than on cow peas. Farther north the seeds should be sown thicker, in drills two or three feet apart, or broadcast at the rate of one or two bushels per acre. Its range of profitable cultivation does not extend beyond that of cotton and will not until its period of cultivation has been extended long enough to result in the origination of new varieties suited to a wider range of soils and climates.

FERTILIZERS.



Velvet bean makes its best growth on the lighter, sandy soils. While capable of increasing the amount of nitrogen, it requires a liberal dressing of phosphoric acid and potash in the form of superphosphates and muriate or sulphate of potash. It pays to feed the crop well, because on rich ground the gain of nitrogen through the increased crop of vines is more than proportionate to the added cost of the potash and phosphoric acid.

YIELD.

The yields of hay are about the same as for the best varieties of cow peas on similar soils. The plant grows looser and bulkier, and looks as though it would yield twice as much hay as the cow pea, but experiments, conducted at the Alabama Experiment Station, prove that the superiority in this regard is only apparent. The reported yields range from two to four tons of hay per acre, or more in Florida, where two or three cuttings are made during one season. Farther north, the crop has not the same recuperative ability and can only be cut once. The yield of seed amounts to from 20 to 25 or 28 bushels per acre, about the same as for the most prolific varieties of cow peas.

FEEDING VALUE.

The beans have a high feeding value, as shown by analyses made by the Florida Experiment Station. The air-dried, shelled beans contain 6.29 per cent fat, 18.81 per cent crude protein, and 53.5 per cent non-nitrogenous extract. Cow peas contain 1.4 per cent fat, 55.7 per cent non-nitrogenous extract, and 20.8 per cent crude protein; the peanut 39.6 per cent fat, 15.6 per cent non-nitrogenous extract, and 27.9 per cent crude protein; while soy beans contain 16.9 per cent fat, 28.8 per cent non-nitrogenous extract, and 34 per cent crude protein. Digestion experiments have not been made either with the hay or seeds. Judging from the chemical analyses, they are about equal in feeding value to cow peas, but are of less value than either peanuts or soy beans. An analysis of velvet bean hay made at the North Dakota Experiment Station showed 5.3 per cent crude fat, 16 per cent crude protein, 20.7 per cent crude fiber, and 41.8 per cent non-nitrogenous extract. The plants were just commencing to flower at the time the analysis was made.

VELVET BEAN.

a flowers, *b* pods, and *c* beans.

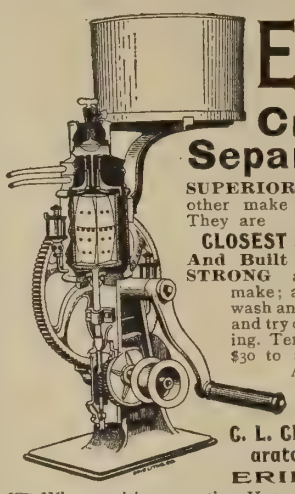
VALUE OF FERTILIZER.

Comparative analyses of the vines, fallen leaves, and roots of the velvet bean, Spanish peanut, and "unknown" cow pea were made at the North Louisiana Experiment Station to determine the amount of fertilizers contained in each crop. For the velvet bean 4,113 pounds of vines and leaves contained 93.4 pounds of nitrogen, worth $14; 3,382 pounds of fallen leaves contained 58.2 pounds, worth $8.73, and 173 pounds of roots, without any stubble, contained 2.7 pounds, worth 40 cents, making a total of 154.2 pounds of nitrogen in the velvet beans produced on 1 acre of ground, worth $23.13. An acre of peanuts contained 193 pounds of nitrogen, worth $28.95, while the 108.5 pounds of nitrogen in an acre of cow peas was worth $16.26. Similar analyses have been made at the Alabama Experiment Station. Here a yield of 8,240 pounds of cured vines and fallen leaves and 1,258 pounds of roots, including about 3 inches of stubble, contained 201 pounds of nitrogen, worth, at about 15 cents per pound, $30.15. There was 2.29 per cent nitrogen in the cured vines and 1 per cent in the air-dried roots.

Experiments were also made at the Alabama Station to determine the value of the velvet bean as a fertilizer, judging from the yield of succeeding crops of oats and sorghum. The increased yield of sorghum fodder was 3,272 pounds per acre over the yield on the plat which had not been cropped the previous year—something over 1½ tons, valued at $12. The yield of oats grown on land where velvet bean stubble had been plowed under was 38.7 bushels, and where velvet bean vines were used 28.6 bushels, while land on which a crop of crab grass and weeds had been plowed under only yielded 7.1 bushels, an average gain of 26.5 bushels of grain as a result of growing velvet beans on the land the previous year. The average gain was about the same when cow peas were grown.

It is harder to plow under a crop of velvet beans than one of cow peas, on account of the tangled mass of vines. It is necessary to use a rolling cutter, unless the farmer has a disk plow. At the Alabama Experiment Station it was found that as good results were obtained from plowing under the stubble as from plowing under a full crop of vines. As a general rule, it may be considered a wasteful practice to turn under the entire crop, because the feeding value of any leguminous crop is always greater than its fertilizing value. A greater profit can be secured in the form of marketable meat products without materially lessening the influence of the leguminous crop on the succeeding one in rotation.

VELVET BEAN.



Showing leaves, flowers and young pods.

USE OF THE BEANS FOR FOOD.

Velvet beans have been used to some extent as human food. The general opinion, as expressed by correspondents of the Southern agricultural papers, is that they are richer and less palatable than cowpeas.

The seeds are large, difficult to thrash, and the pod does not break up readily. Special machines have been constructed for the purpose of cleaning them. For feeding purposes it is a good idea to grind them up, pods and all, thus saving the expense of threshing. The meal may be used as a concentrated feeding stuff in the same manner as cottonseed meal. It is said that cattle, sheep, hogs, and poultry are all very fond of them, but horses apparently do not relish them.

SWAMP-ROOT Is not recommended for everything; but if you have kidney, liver or bladder trouble it will be found just the remedy you need. At druggists in fifty cent and dollar sizes. You may have a sample bottle of this wonderful new discovery by mail free, also pamphlet telling all about it and its great cures.
Address, Dr. Kilmer & Co., Binghamton, N. Y.

Eclipse Cream Separators

Advocates Millet.

ED. HOARD'S DAIRYMAN:—Your reply to G. L., of Adams, Wis., inspires us to say a good word in regard to millet. It is gaining favor here among dairymen as a forage crop for milch cows. It also makes excellent winter feed if cut at the right time and properly cured. The German variety is the favorite here, and is usually sown in June. The hay crop is light and millet and fodder corn will have to supply the deficiency. L. W. G.

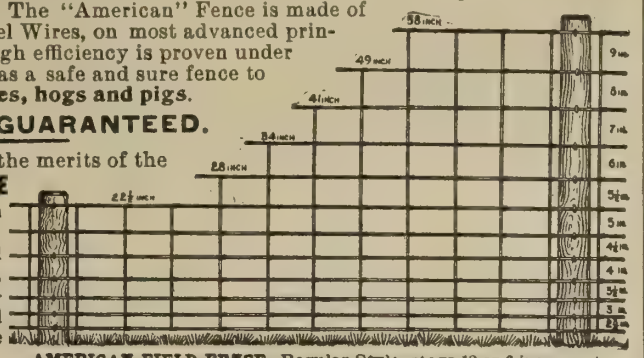
Bouckville, N. Y.

Good Bulls.

Experiments Showing the Importance of Superior Sires.

One of our Kansas creamery patrons, says Prof. D. H. Otis, had two heifer calves in succession from an old red cow, one by a Holstein and the other by a Shorthorn. In a seven days' test the Holstein heifer with her third calf, produced 2.3 pounds of butter per day, and for the same time the Shorthorn, with her second calf, produced 1.2 pounds of butter per day, the Holstein giving milk 11 months of the year and the Shorthorn only five months. This speaks very emphatically as to the value of a good sire in raising dairy cows.

The dairy business is far more overdone by the "average" cow than from any other cause. The trouble is she eats and exists upon a man's farm to do just half what is required of her, and eats as much good food in the year as her betters. The amount of milk this average cow gives is 3,100 pounds yearly, and it should be as many quarts of better milk. If one looks at this average cow critically, the signs are too often reversed from what they should be—viz., her head is too large to correspond with her udder, her shoulders wider than her hips, and her tendency is to put tallow upon her caul and not in her milk. She has ample storage capacity for everything except milk. She is a parasite that eateth by noonday and wasteth a man's substance by night, and in the way of "fleecing the innocents" she beats all the trusts and rings combined.—*San Francisco Chronicle.*



THE FENCE THAT FENCES.

"AMERICAN" ALL STEEL WOVEN WIRE FIELD FENCE.

Large, strong wires heavily galvanized. **Tension curve** at every intersection of main strands and stay wires, provides for expansion and contraction. The "American" Fence is made of Best Bessemer Steel Wires, on most advanced principles. Its thorough efficiency is proven under all circumstances as a safe and sure fence to **turn cattle, horses, hogs and pigs.**

THE NEW BOOK

Feeds and Feeding

By Prof. W. A. HENRY,

Wisconsin Experiment Station.

This book should be in the hands of every stock feeder in the country. Every reader of HOARD'S DAIRYMAN ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehensive from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be referred to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price, $2.00.

A Perfect Milk Wagon

On a Perfect . . . Short Turning Gear

WE make the only drop center wagon that has a self-balancing, short turning gear. All parts are wrought iron forgings. It is so plain and simple that it can't get out of order and if any part should break, any country blacksmith can easily repair it. All other wagons of this kind have complicated gears, and mostly made of cast iron.

Write us for our Catalogue, which fully illustrates and describes this wagon and 10 other styles.

Nashville, Tenn.

MAKE ONLY

SWEET ENSILAGE

Ever since the ensilage system has been introduced in this country it has been the ambition and effort of siloists to ***produce sweet ensilage.*** The making of sweet ensilage depends principally upon two things—***1st.*** the use of a well matured crop and ***2nd.*** upon low fermentation. Granting the maturity of the crop, shredded ensilage makes the sweetest ensilage. The reasons are, that shredded material is of a nature that makes it pack much more closely in the silo. That means exclusion of air; there can be no extreme fermentation and consequent development of acid without the free action of the air. ***Shredded ensilage possesses other advantages in addition to its sweetness:—*** it is eaten with great avidity by animals, being a long, soft substance and free from any sharp angles and corners to cut or lacerate the mouth and gums; it is therefore fed with less waste.

The best way to Shred Ensilage is with the

St. Albans Ensilage and Fodder Shredder.

It is the Original Shredding Machine and all other so-called shredders are merely imitations of this one. ***It will certainly pay you*** to look into the merits of this proposition and machine before buying. We mail a pamphlet on the subject.

HANEY-CAMPBELL COMPANY, - Dubuque, Iowa.

The Home of Blaine.

The state of Maine is rapidly coming to the fore in its dairy interests. The Turner Center Dairy Association, of Auburn, Me., is one of the largest manufacturers of butter in America. An immense five story building; machine y the very latest and best; their plant is worth a visit, as it is the most complete of its type in America. **Of course they use the Sharples Factory Separators exclusively.**

At Dexter, Me., another great factory, operating on the same system, has lately been fitted up with new separating machinery. A thirty days' trial of Separators was inaugurated before finally deciding on a purchase. The **Sharples Tubular,** the Alpha, and one other make were placed side by side for trial. The following from a letter dated, Dexter, Me., May 26th, tells the story:— **"The De Laval man has boxed up his machine and sent it back home; they could not make it do the work the Sharples Tubular is doing."**

THE TUBULAR SEPARATOR

MAKES THE FINEST CREAM;
MAKES THE MOST BUTTER.

It is the safest separator. It is the simplest separator. The revolutions are high but the speed is low. But what we say or what others say don't count so much as the actual performance of the machine. You can have one to try.

Send for Catalogue No. 46.

It Does Not Destroy the Grain.

THE SQUEEZER COMBINED CHURN AND WORKER
will do exhaustive churning at any desired temperature. It **makes a superior quality of butter,** distributes the salt evenly and **prevents mottles.** It belongs in every dairy turning out high grade work.
IT IS SIMPLE, DURABLE AND EASILY WASHED.

Made in a series of Desirable sizes.

We are prepared to repair all cream separators and employ highly skilled men for this work. Send at once for our Catalogue, No. 82.
Address, ELGIN MANUFACTURING CO., ELGIN, ILLS.

SOME DISBROW POINTERS

It has taken us several years to convince the buttermakers of this country of the value of combined machines. The DISBROW was the first machine put on the market. Imitators and infringers have been numerous, but today the DISBROW is the only UNIVERSALLY SATISFACTORY machine. Why? Because every buttermaker who has used one knows that he can make MORE BUTTER, make BETTER BUTTER, and make it EASIER with a DISBROW than with any other kind of churn and worker. Are you one of those who are not yet convinced of the merits of the DISBROW? Don't condemn it. Write to us and we will refer you to hundreds who are using DISBROW machines, and believe they are the modern wonder in creamery machinery.

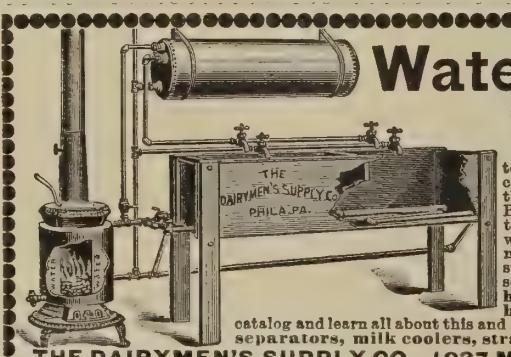
Condensed... Milk Factories



Built Complete By

Special Attachments not shown.

C. T. ROGERS & SONS, Detroit, Mich., U. S. A.

We are the only firm that builds factories complete, put them in operation and guarantee results.

Water MUST Be Hot

to properly clean and scald **your milk** cans, pails, strainers and bottles. With this Hot Water Stove, Circulating Boiler and Wash Box, you can have the water as hot as you want it, just when you want it. Little expense and no trouble to run it. The hot water stove, with pipes and fittings furnished separately. **Best and cheapest heater for greenhouses, hen houses or hog pens.** Write for free catalog and learn all about this and many other dairy necessities—**cream separators, milk coolers, strainers, scales and butter tools.**

THE DAIRYMEN'S SUPPLY CO., 1937 Market St., Philadelphia.

Is it **CHANCE,** is it **GOOD LUCK,** or is it **MERIT** that has enabled the patrons of

GENESEE SALT

for five years in succession to win the SWEEPSTAKES PREMIUM of the NATIONAL CREAMERY BUTTERMAKERS ASSOCIATION? Certainly they were good buttermakers, but perhaps the Salt had some little to do with the result. The winners were as follows:

In 1895.....F. G. OLTROGGE
In 1896.....THOS. MILTON
In 1897.....H. N. MILLER
In 1898.....S. HAUGDAHL
In 1899.....R. T. MCCOLL

Study your own interests, use **GENESEE SALT,** and write to Mr. F. A. TRIPP, No. 34 Clark Street, Chicago, for Entry Blank for the **1899 GENESEE EDUCATIONAL CONTEST.**

Yours truly,

THE GENESEE SALT COMPANY, New York.

Subscriptions in United States, Canada and Mexico $1.00 per year; 6 months 50 cents; 3 months 25 cents.

Foreign Subscriptions may be sent through Sampson Low, Marston & Co., St. Dunstan's House, Fetter Lane, London, Eng., or their agents including the leading news dealers and book sellers in nearly all foreign countries.

All countries in the Postal Union $2.04 a year; not in the Postal Union $2.56.

Correspondents must not expect us to acknowledge the receipt of letters containing remittances for subscriptions. The receipt of the Dairyman is sufficient notification that the money has been received. The label on the paper will show date to which subscription is paid. In case of renewals if date on label is not changed within two weeks after remittance is sent, inform us at once.

Remit by draft on Chicago or New York, or Post Office or Express Order; never by personal check.

ADVERTISING RATES.

Twenty-five cents per line, (agate measure) 14 lines per inch, each insertion.

Reading notices, 50 cents per line (nonpariel measure) each insertion

It is announced that H. B. Gurler, of De Kalb, Illinois, who is one of the most accomplished and practical dairymen of the United States, will make an exhibit of his method of handling a dairy farm at the Paris Exposition next year. Mr. Gurler's dairy product is sold in Chicago at twelve cents a quart, and the business is conducted on such a scale that it requires eighteen men to milk the cows.

Accompaning the two cuts given on this page are letters from the owners of the animals, giving details of their performance. As is well known, the Dairyman has insisted that form was an indication of performance and that in proportion as the animal showed development in certain directions, so would her production be. In this case where both the form of the animal and her performance can be compared, our readers can easily observe to what extent theory and practice are companions.

SILO EXPERIENCE AND ADVICE WANTED.

Hoard's Dairyman would be particularly obliged if a score or more of its readers, who have had four or more years experience with the silo, would favor it with brief suggestions, founded upon such experience, as to the best methods of constructing and filling silos. They have doubtless learned some things which it is desirable to avoid and oftentimes this is most valuable information, and hence the main question practically takes the following form:

If you were to build a silo this year what departures (if any) would you make from the style or styles heretofore in use, and why?

Experience with stave silos and with silos with cement linings and with the use of the shredder in place of the ordinary cutting box, is especially desired.

WILD TALK.

Because in one herd, Springfield, Ill., of forty-six cows, twenty-five were found to respond to the tuberculin test for tuberculosis, the newspapers of Illinois seem to have gone wild on the subject. The *Springfield News* says in glaring head lines that "most cows have tuberculosis" and it declares that "almost one third" of all the cows from which milk is taken to consumers in that city are affected with tuberculosis.

A wise man once remarked that "on all those subjects that cannot be proved there is the most discussion."

The latest deductions of science and the average of all investigations show that not five per cent of the cows are affected by tuberculosis and not one in a thousand of those cases convey the disease through her milk. It is time that a little common sense was injected into boards of health and veterinarians on this question.

An Iowa Grade Jersey.

Ed. Hoard's Dairyman:—I herewith send a picture of a grade Jersey cow (31-32 Jersey) descended from good native stock. She is now nine years of age, and in 1894 made 399 pounds butter; in 1895, 345 pounds; in 1896, 399 pounds; in 1897, 401 pounds; in 1898, 280 pounds. I can give no reason for the variation, other than my cows are like apple trees, have their off years. I have other cows that have done as well, and better, all descended from the same source. For the past six years, the milk of each cow in my herd has been weighed twice a month, and tested once a month. This cow never dropped a male calf.

Springville, Ia. J. L. Hoyle.

GRADE JERSEY COW.

Property of J. L. Springville, Iowa.

Chemical analysis of the butter made by L. W. Pierce, of Pomona: Water 11%, ash 2.6%, casein 1.7%, fat 84.7%.

Babcock test, fourteen samples, average 5.2%, total butter fat 14.3968 pounds; estimated butter fat by adding 1/6 to total fat, 16.7958 pounds. The cream was separated after each milking, and two churnings made.

The cow freshened February 19th, 1899, and gave from February 21st, to May 1st, (seventy days) 2,849 pounds, 7 ounces. Her greatest milk yield for twenty-four hours, 52 pounds, 1 ounce, on March 15th; for forty-eight hours, 103 pounds, 10 ounces, March 15th, and 16th; from March 13th, to March 19th, inclusive, she gave 349 pounds, 2 ounces of milk.

I enclose memoradum of Babcock test made during butter test. The great variation in amounts of milk and fat, is due to the very trying weather of that week. The first three days were very cold, and a sudden hot spell followed, during which the themometer reached 104°. The cow also came in heat unexpectedly, which also helped to lower her record. No previous preparation, as to feed, was given. During the test she was fed bran and corn meal in equal parts, amounting in the seven days, to 107 pounds, with alfalfa hay and mixed pasture *ad libitum*.

Terry's Pet has the typical dairy conformation, which you so strongly advocate. She is a cow of enormous digestive capacity, and a grand individual, and a very persistent milker.

I hope later to give you a more extended account of my dairy herd, many members of which have produced over 400 pounds, one reaching 526 pounds in eleven months and a half. This result in selecting and feeding my cows is entirely due to the teachings of Hoard's Dairyman, which has been my constant adviser. J. Lansing Lane.

Rincon, Calf.

JERSEY COW, TERRY'S PET, A. J. C. C. 96851.

Property of J. L. Lane, Rincon, Cal.

Test of a California Jersey.

Ed. Hoard's Dairyman:—Under separate cover, I send you two photographs of my cow. Terry's Pet No. 96850 A. J. C. C. She has just completed a seven days' butter test, conducted by Mr. C. S. Burgess, of Arlington Place, in accordance with the rules of the A. J. C. C. Besides the churn test I made a Babcock test of each milking, and you will note how nearly the results coincide.

The test commenced April 3rd, a. m., finished April 9th, p. m. Amount of milk given, 278 pounds, 2½ ounces. Unsalted butter churned, 18 pounds, 11½ ounces. Salt added, 18½ ounces. Reworked butter, 16 pounds, 13 ounces.

WHAT IS THE MATTER?

On page 410, last column, in his most excellent address on the "Value of Breeds", Prof. G. M. Gowell, of Maine, states some practical facts from the farm end of the creamery business as it appears in Maine. He shows from actual statistics that certain Maine farmers obtained as high as $60 per cow from the creamery, while others got no more than $20, and he tells the reason why. It is the same in Maine as it is in Wisconsin, and the reason is a sad lack on the part of the $20 farmer of a "saving knowledge" of what constitutes a dairy cow, how to breed that cow, how to care for, and feed her so she may do profitable work. In its investigation among patrons of creameries, Hoard's Dairyman has found at least a hundred $20-per-cow men where it has found one $60 one.

It is this low state of knowledge, ambition, pride, and all that makes up a first-class farmer and dairyman, that is at the bottom of all ill luck and discouragement, these men meet.

They realize that they are making no money, and yet they never turn their eyes inward to see the cause.

They kick vigorously at the creamery, the transportation companies, the commission men and everything but their own lack of dairy knowledge. And so long as they continue in this frame of mind and keep in partnership with the "twenty dollar" cow, their kicking will bring them no relief.

A Silo in a Cistern.

Ed. Hoard's Dairyman:— I have on my property a solid mason work structure of the following dimensions: 19½ feet long, 13 feet broad, 6 feet 9 inches deep. Can I use this for making a silo without increasing the depth? To make it deeper will cost a good deal of money, and as I said in my previous letter, silage is only in its infancy in Jamaica, and our cows may require a lot of "training" before they will eat it. Therefore I should like, if possible, to use this structure just as it is.

If you think I could make silage in it, what weight would I have to use on the top of the silo, i. e., how many hundred pound weight to the cubic foot?

How many tons of fodder would such a silo hold?

What kind of covering should I have over it?

I shall be glad to hear all the information you can give me on the subject.

Jamaica. H. Farquharson Kerr.

A silo of the above dimensions will be very liable to spoil a large per cent of the silage, unless special precautions are taken to cover the surface with boards and tar paper, so as to exclude the air as much as possible, and then weight heavily. Even then it is doubtful whether it would pay for the extra work, as a tank of the above size would not hold more than twenty-five tons of silage. It would be better, in the long run, to build a square silo, using the tank as a foundation, and making the wooden part at least fifteen feet high, and twenty feet if possible. The weight of the silage would then do all the pressing necessary, and if the surface of the silage is covered with a foot or so of coarse hay of any kind, it will form a sufficiently tight cover.

If you wish to use the tank alone, cover the silage well with boards and tarred paper, and weight with stone at least fifty pounds to the square foot.

In feeding the silage, remove the cover in short sections, and cut the silage down at the end, as used, so as to leave as little surface exposed as possible.

The creamery at Turner Center, Maine, has taken up the business of separating the patrons' milk and shipping the cream, instead of manufacturing it into butter. Ten and a half tons of ice are chopped up daily by a machine and packed about the cream, which is enclosed in ten gallon cans, each can being enclosed in a wooden box and the space between the can and box filled with ice.

ON another page of this issue, a correspondent gives the increase in cream from the addition to the comfort of the cows by stabling in hot weather and thus protecting them from heat and flies.

Small things affect the yield of milk and butter fat, and an uncomfortable cow will not do her best, no matter what food is given her.

DOING GOOD WORK.

Telegrams to the daily papers report that the Wisconsin Dairy and Food Commissioner has instituted prosecutions against several milk dealers in Beloit, for using "preservatives" in milk. Some of them have pleaded guilty and paid their fines and others propose to stand trial.

The use of "preservatives" in milk is not only a violation of the laws of Wisconsin, but is a reckless disregard of the rights of the consumers of the milk, because it is a menace to their health. That such things do not kill the victim instantly or produce immediate illness, does not by any means disprove that they contain dangerous ingredients. No well informed person would knowingly use milk that has been "embalmed."

FORM IN FOWLS.

There are yet too many people who do not accept the proposition that nature is always striving for the lines of least resistance, and, therefore, wherever it can, is adapting form to function. HOARD'S DAIRYMAN has been laughed at, sneered at, and made the butt of many a poor joke because it has insisted that there was such a thing as dairy form. The facts have all the time kept coming our way, and the doubters and disbelievers are becoming fewer every year.

In fact, the principle for which we have contended is being applied in many new ways, one of the latest being the selection of fowls according to form, and distinguishing between the fowls whose special purpose is egg production, and those better adapted for meat production. The former have a longer and slimmer body, heaviest in front, but with a thin neck and small head; the latter have a square, compact, closely knit body, indicative of more rapid growth and less waste in dressing.

VARIATIONS IN THE DAILY TEST.

Patrons of creameries frequently write to the DAIRYMAN concerning variations in the daily test, as shown by the Babcock test.

They do not understand that the per cent of fat in a cow's milk is not a constant, but a variable amount, and are apt to question the accuracy of the test itself or the honesty of the person performing the operation.

We would call the attention of those who have had such experience, to the following table, sent by the owner of Terry's Pet, and compare it with the account of the test given on page 447 of this issue.

The wide variations in milk, per cent of fat and total fat are very noticeable, and serve to emphasize how little things, affecting the condition of the animal, are recorded in the yield of fat. Following is the table:

April 1899.		*Milk.*	*Test.*	*Pounds Fat.*
3	a. m.	22 lbs. 15 oz.	4.2%	.9633
	p. m.	22 " 8 "	4.9%	1.1025
4	a. m.	22 " 7 "	4.7%	1.0545
	p. m.	21 " 14½ "	5.5%	1.2048
5	a. m.	20 " 15 "	5.1%	1.0678
	p. m.	19 " 6½ "	5.2%	1.0091
6	a. m.	18 " 6½ "	6.2%	1.1418
	p. m.	16 " 14½ "	6.3%	1.065
7	a. m.	19 " 6½ "	5.8%	1.1255
	p. m.	18 " 10½ "	4.7%	.8768
8	a. m.	18 " 10½ "	4.3%	.8022
	p. m.	19 " 2½ "	5.5%	1.0536
9	a. m.	18 " 14½ "	4.8%	.9075
	p. m.	17 " 15 "	5.7%	1.0224
		287 lbs. 2½ oz.		14.3968

Average test 5.2%.

A REPLY TO MR. GASTON.

Some Aspects of the Proposed Law for Taxing Colored Oleomargarine.

Mr. Gaston's communication, printed elsewhere in this issue, doubtless voices the sentiment of a very considerable number of people who have so little sympathy with frauds of any kind that they insist upon a purely prohibitive law and will assent to nothing less than this.

It would be entirely foreign to the long established practice of HOARD'S DAIRYMAN to discuss this subject in its relations to the liquor traffic, or attempt to prove or disprove Mr. Gaston's allegations. We have prohibitive laws in regard to oleomargarine in thirty-three states, but through the laxity or connivance of the officers whose duty it is to enforce these laws there are large areas in every state where they are practically inoperative, and it is at least doubtful whether any state law could be made operative to exclude oleomargarine or whiskey, purchased in one state and transported to another for private use. There is also the further trouble, expense and uncertainty of trying to follow up and convict a hundred or a thousand retailers. In short, it has to be admitted that state laws are not adequate to search and suppress the oleomargarine fraud even within the borders of the state. Nothing less than a strict search of every car, boat and wagon that crosses a state line would suffice for this purpose.

It is one of the maxims of the law that there is, or ought to be, a remedy for every wrong. This proposition is written in many of the state constitutions, and in Wisconsin is thus expressed:

"Every person is entitled to a certain remedy in the laws for all injuries or wrongs which he may receive in his person, property or character; he ought to obtain justice freely, and without being obliged to purchase it, completely and without denial, promptly and without delay, conformably to the laws."

What we ask, therefore, is that congress shall come to the help of the states, in such ways as it can under the constitution of the United States. Confessedly congress cannot enact a prohibitive statute *per se*, but it has "power to lay and collect taxes, duties, imposts and excises" and this too, contrary to common belief, without regard to the specific purpose of raising revenue. This conclusion is well exemplified in several of the tariff schedules, in the law taxing the circulation of state banks and in many other less notable instances. The only restriction is that "all duties, imposts, and excises shall be uniform throughout the United States."

It is, moreover, a mistake to suppose that the laying of a tax, duty, impost or excise upon any article or occupation thereby "legalizes" it or confers upon it any standing it does not otherwise possess, and least of all can an act of congress override, annul or repeal a constitutional state law. Not to multiply instances, it suffices to cite the case of the prohibitive laws of Maine, which are enforced with more or less thoroughness, notwithstanding the circumstance that the articles whose sale is prohibited have been taxed for more than thirty years by the United States. Oleomargarine itself has been taxed without regard to color for many years, but this gives no one a right to sell it contrary to state laws.

The only remaining questions, as it seems to us, are, will the imposition of a ten cent tax on colored oleomargarine tend to restrict its unlawful sale in the states where such sales are forbidden by local statutes, and if so, is such restriction desirable.

The manufacturers of oleomargarine, and all those who sympathize with them, their allies and attorneys will answer the last question in the negative. The *people* in thirty-three states, speaking through their legislatures, have answered it in the affirmative. It is a case of a few millionaires and their retainers, great and small, against the the people, including a hundred times more consumers of dairy products than dairy farmers. It is a gross misuse of terms to call this "class-legislation." In fact, not to pass some operative law in this behalf is class legislation of the most restricted kind. Not to do the proper thing is as gross a fault, as to do an improper thing.

What will be the probable effect of a United States tax of ten cents a pound on colored oleomargarine? Certainly this, if nothing more. It will bring the cost of the stuff to the manufacturer so near to the cost of butter, that he cannot afford to take many chances for conviction in the state courts for violating state laws. He will not, for instance, come into Wisconsin and say to dealers in Racine, Milwaukee, Ashland, Superior and elsewhere, "go ahead and violate the laws of your state, and if you are detected, prosecuted, convicted, and fined, we will pay the fine, and all the costs and expenses to which you may be subjected."

It will do another thing, which these millionaire sympathizers with their so-called poor laboring men are professedly so anxious about. It will enable every one who wants oleomargarine, to buy it for what it is, and what it is worth, and prevent him from being cheated by having oleomargarine imposed upon him for butter, and at butter prices.

It may serve as an actual prohibition of the sale of colored oleomargarine anywhere, just as the imposition of the ten per cent tax on state bank currency wiped that monstrosity out of existence years ago. And if it should, the mourners would be chiefly conspicious for their infrequency.

A Slander on Guernsey Cattle Refuted.

Although appreciating your reluctance to discuss the relative merits of breeds of dairy cattle, I venture to make the following inquiries trusting that you will be kiud enough to enlighten me if possible, through the columns of your valuable paper. It has come to me recently as the statement of a well known breeder of Guernsey cattle, confidentially made, that Guernseys as a breed are more difficult to get in calf and more subject to abortion than other thoroughbreds.

As I have recently purchased two thoroughbred Guernsey heifers from H. McK. Twombly, with the intention of breeding them to my thoroughbred Guernsey bull, Pasha No. 4860, as a nucleus for a small herd of thoroughbreds in addition to grade cows, I am anxious to get all the information I can in regard to the chances of making a success with my venture. Any statistics you could give me I should greatly appreciate.

Southville, Mass. R. F. P.

There are several herds of Guernsey cattle in our immediate vicinity, and others in Wisconsin and elsewhere with which the editors of HOARD'S DAIRYMAN are well acquainted, and it gives them pleasure to state from personal knowledge, corroborated by reliable information that there is no foundation, whatever for the statement above attributed to "a well known breeder of Guernsey cattle." This gentleman may have had these troubles in his own herd as others have with other breeds, but such instances are the exceptions and not the rule.

ON account of insufficient appropriations by the legislature, the trustees of the Pennsylvania State College have been compelled, along with other measures of retrenchment, to discontinue for the present the twelve-weeks Winter Lecture Course in Agriculture and the Cheese Making Course. The Creamery Course will be given as heretofore, beginning January 3d, and the work of the regular four years course, and of the special one year course, will go on as usual. Special efforts will also be made to increase the efficiency of the Correspondence Courses in Agriculture.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

FEEDING STANDARDS FOR MILCH COWS.

Dry matter.	DIGESTIBLE NUTRIENTS *Protein.*	*Carbohydrates.*	*Ether extract.*
lbs.	lbs.	lbs.	lbs.
23 to 28	2.0 to 2.5	12 to 15.0	0.5 to 0.8

AN ONTARIO RATION.

Which is the cheapest and best feed for dairy cattle during autumn and winter of the following, and at the prices named, accompanied with provender composed of peas and oats, which we produce on our own farms: Gluten meal at $18.00 per ton, cotton seed meal at $25, bran at $14, shorts at $15.

How much of a balanced ration should be fed to cattle, say of 900 weight, of the above mentioned feeds, accompanied with clover hay and timothy, per day. By kindly answering those questions you will oblige your oldest subscriber in this section.

Ontario. A. M. C.

The peas and oats alone would answer very well with clover and timothy hay. If mixed in equal amounts by weight they would contain digestible nutrients as follows:

Protein.....13.0 per cent
Carbo hydrates.....49.5 "
Fat (ether extract).....2.5 "

This does not differ very materially from

good bran, except in the carbohydrates, which is much the cheapest nutrient. It follows, if the peas and oats are worth much more than the cost of bran, it would not pay to feed them except in limited amounts and for the purpose of providing a variety in the ration.

The following formula suggests a ration that ought to produce very satisfactory results:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
18 lbs. mixed hay.....	15.44	.86	7.13	.29
3 lbs. peas and oats..	2.69	.28	1.49	.08
4 lbs. bran.....	3.52	.50	1.54	.12
2 lbs. cotton seed meal	1.84	.74	.34	.18
Totals.....	23.49	2.38	10.50	.67

FLY REPELLENTS—WHAT TO FEED WITH SKIM MILK.

The annual battle between the cows and the flies is now about to commence. The prepared articles are quite expensive and not altogether effective. Can you tell us of some mixture that we can make and the manner of applying it, that will materially assist the cows in this unequal contest.

We have sweet skim milk that we want to feed to sows and little pigs and also to weanlings, pigs and young hogs. What should we add to the milk to secure the greatest benefit when fed to these various kinds of swine. Give the proportionate rate of weight of each part of the feed for each kind of animal. T. E. E.

Fort Wayne, Ind.

The fly-repellent question is discussed in answer to an Ontario reader.

For the sows, mix ground oats, corn or middlings, or a mixture of them, with the skim milk in the proportion of one pound of the grain to 5 to 7 pounds of the milk. If the sow is an abundant milker and grows too thin, increase the proportion of grain. For young pigs, clear skim milk at first, adding grain gradually until it reaches the proportion of one part to three or four parts milk.

CHANNELS OF INHERITANCE.

A prominent, intelligent and successful breeder of dairy cattle maintains that a male calf inherits to a greater extent the qualities of its dam than of his sire, and that a female calf inherits the qualities of her sire more than of her dam. What does the DAIRYMAN say? A. M. C.

Ontario.

The DAIRYMAN says that its editors have observed many instances which seem to corroborate the "rule" above set forth, but on the other hand there are so many instances where this rule does not obtain that it is impossible to accept it as the final guide.

FEEDING DAIRY COWS IN GEORGIA.

I am now feeding my cows four pounds cotton seed hulls mixed with two lbs. cotton seed meal, two pounds pea meal, 2 pounds corn meal, 3 pounds bran, one day's ration, and fed to the cows in two parts, morning and night, with sorghum (early amber corn) and all the dry corn fodder, crab grass and pea vine hay they will eat. Is this ration right? J. W. D.

Cuthbert, Ga.

We do not see any way in which to improve upon the foregoing as an average. It it a pretty full ration—more than a cow much below her maximum yield can use to profit, but less than very many cows could utilize when at their best. When a cow commences to lay on superfluous fat, it is time to reduce her grain allowance, but as long as she uses her feed for making milk, one may be sure he is not overfeeding,—provided, always, that the ration contains sufficient protein to enable her to keep the milk making machinery properly supplied with the raw material out of which the milk is made. In this case the allowance of protein appears to be ample.

FLY REPELLENTS.

An Ontario reader wants to know the *best* remedy for the horn fly. An editor is in much the same position as a witness in a court of justice and needs to be quite as careful in giving expression to his opinions.

There are several excellent preparations for repelling flies of all kinds. Whatever will keep off other flies will also repel the horn fly. As will be seen in his communication in another column, "Buff Jersey" sets great store by the preparation called Shoo Fly, that has been advertised in the DAIRYMAN for several years. The editors have also used it with great satisfaction. Other preparations, ready for use, are on the market, and recipes for home-made mixtures have been published in recent issues.

WHAT SHOULD BE THE AVERAGE YIELDS.

Please advise me how many gallons of milk a herd of carefully selected Jerseys and grade Jerseys should average per cow the year round, cows to come fresh every twelve months; also give me the average of Durhams. T. G. S.

Norfolk, Va.

A herd of Jerseys and grades could not be called carefully selected if it contained any mature animals that would not yield with proper feed and care 600 gallons of milk every twelve months. This amount of milk, testing 5 per cent fat, would suffice for making 300 pounds of butter. Cows whose milk habitually tests below 5 per cent fat should be required to yield proportionally more milk, and those whose milk runs above 5 per cent might be tolerated if they did not quite reach the 600 gallons. A similar rule should apply to Durhams, (Short horns,) if kept for dairy purposes, subject, possibly to the slight deduction incident to the circumstance that the Durham calf is likely to weigh a few more pounds at birth than a Jersey or grade.

SIZE OF SILO FOR TWO ACRES OF FLINT CORN.

I have been a reader of your paper for five years, and it is a prize for me.

I would like to know, through your paper, how large a round silo I want twenty-two feet deep, to hold two acres of our flint corn, not cut or cut up, rows three feet apart, hills two feet apart. F. H. L.

Dinfield, Me.

A round silo ten feet in diameter and 22 feet deep will hold approximately 30 tons of silage, and this is probably more than one could expect, year after year, from two acres of common flint corn. We would not advise building less than ten feet in diameter and would prefer to have it twelve feet.

REMOVING DISEASE GERMS WITH THE SEPARATOR.—EFFECT OF PASTEURIZATION ON BUTTER.

Does separating remove all disease germs from cream?

What effect will pasteurizing the cream have on the butter? N. S.

Rockdale, Ill.

No. The separator will remove an immense number of bacteria from the milk and concentrate them in the separator slime, but there are enough left to cause the milk or cream to be dangerous if any disease germs are present.

Pasteurization gives a longer keeping, lighter flavored butter. The grain is also liable to be poorer in quality unless special precautions are taken as to cooling the cream before churning.

SILO QUESTIONS.

Will cement stay on a wall of earth, clay, sand, etc. I want to build a silo and dig in ground eight or ten feet and put a stave silo above. If I can do this, what size should I build and how many pieces of lumber and what size will be best for a silo for twenty milk cows, fifteen heifers and calves, seven horses, for at least six months in year. I would like to dig in ground eight or ten feet.

Where can I get iron lugs from, I mean for the hoops? J. B.

Greenville, N. C.

It will depend on the thickness of the coat of cement and the nature of the soil.

In some places in the South pit silos have been dug in a very stiff, tenacious clay soil and lined with a coating of cement. But this would not work in a sandy or gravelly soil unless the coating of cement was heavy enough to resist the thrust of the soil, and for this purpose a stone wall built with cement would probably be cheaper.

For details regarding building a stave silo, see page 267 of present volume and if further information is desired send to Cornell University, Ithaca, N. Y., for their bulletin on "Building a Stave Silo."

The number of head of stock you mention will require at least 100 tons of ensilage, requiring two silos 15×20. Two silos are better than one large one, as there is less loss from the surface of the silage molding during feeding.

Unless you have the right kind of soil for a pit, it will be cheaper to build above ground.

For silo fittings address Geo. D. Harder, Cobleskill, N. Y., and Williams Mfg. Co., Kalamazoo, Mich.

ALABAMA FEEDING PROBLEMS.

Will you kindly advise me when and how to plant rye and clover for winter pasture. How much of each of the above seed per acre, would you use? Where can I get the seed from, and what kind of clover would you use?

I am feeding wheat bran, at $18 per ton; corn meal, at $22 per ton; cotton seed meal, at $18 per ton; best timothy hay, at $12.50 per ton and cotton hulls, at $5.00 per ton. Kindly make a ration out of the above and oblige. I give the cows all of the green sorghum they will eat up clean, cut up fine, say one-half to one inch in length.

Mobile, Ala. P. R. T.

We are hardly competent to advise as to dates for sowing either rye or clover for winter pasture, as far south as Mobile. Under favorable conditions, rye will be fit for grazing in about four weeks from seeding. Clover will take much longer. In fact, we could hardly advise pasturing clover very much the first season. We would not think of pasturing at all for four months. Sow rye at the rate of two bushels per acre, and clover seed at about twenty pounds. We should use the common red clover, although not at all certain that crimson clover would not be better for the extreme south. It might not be amiss to correspond on this subject, with the Director of the Alabama Agricultural Experiment Station, which is located at Auburn, in that state. Any seed merchant can furnish the seed.

While the sorghum lasts, give in connection with it all the good hay and hulls the cows will eat, and from six to ten pounds of grain. With the smaller quantity, limit the cotton seed meal to two pounds, and in no case let it exceed three pounds. We should use but little corn meal, and none at all, except to such cows as were disposed to keep too thin in flesh.

It occasions us no little surprise, that in a section so well adapted to corn as the southern and gulf states, that corn products of all kinds should rule so high. More corn and less cotton would be a profitable change on many farms and plantations.

COST OF MAKING BUTTER.

Ought not butter fat to be worth the same price per pound as butter sells for? In other words, if I furnish milk and separator, and the butter maker runs the separator, makes and sells the butter, ought not the increase to pay him as well for labor, etc., as it does me to furnish the milk, etc? To make it more plain; I, with others, put up a skimming station and furnish it with the best separator and fixtures. The butter maker is at all expense in running it, making and selling the butter made from the butter fat of 3,000 to 5,000 pounds of milk. Ought not the patrons, in justice, to receive as much per pound for the butter fat, as the butter made from it sells for? Will not the one-fourth or one-fifth excess of butter, pay him well for making and selling the buttter fat, etc., etc.

Give us poor ignorant milk producers all the light you can, so that we may learn what is our share, and then we will demand it.

Kansas. A NEW SUBSCRIBER.

The patrons should be paid the market price for every pound of butter made, less the cost of manufacture. This should not be over three cents per pound, and usually less. All money should be divided on the amount of butter actually made, and according to the amount of butter fat furnished by each patron. There should not be an over run of more than one-sixth.

SEPARATOR SLIME.

Will you kindly inform me whether the cream or deposit left on the outside of the U. S. separator bowl, which does not go out after reasonable flushing, is cream and should be put in the cream pail, or should it be thrown out with the skimmed milk? The reason for the above question is that we are going to put in two separators, and do not want to make a mistake in purchasing.

Minn. A SUBSCRIBER.

The deposit left in the sides of a separator bowl consists of casein, together with a small quantity of fibrin and all of the insoluble dirt which the milk may contain. It also contains large quantities of bacteria, and taken all together consists of a mass of impurities. Of course it should never be returned to the cream or milk. There is no difference in separators in this respect.

SOJA BEAN.

Will you let me know through the columns of your valuable paper something in regard to the soja bean?

Where can I procure the seed, and how late can they be sown to get good results?

Also, tell something of the nature of the plant. A READER.

Meridian, Mich.

The Indiana Experiment Station gives the following information regarding the soy bean:

A comparatively new and promising leguminous crop for Indiana farmers is the soy bean. This plant has been succesfully grown in different parts of the state and at several points farther north in the United States. It thrives in good corn soils, and will grow wherever corn can be successfully produced.

Being a quick maturing annual, it will prove especially helpful to those who cannot grow clover. A crop of soy beans can be produced between the spring and autumn frosts anywhere in the state. The soy bean may be grown for pasture, green forage (soiling), for hay, silage or seed. It will yield nine to twelve tons of green fodder, 1½ to 2½ tons of hay, and 10 to 40 bushels of seed according to variety, condition of soil, etc.

Varieties.—If seed is desired, the earlier varieties, only, should be grown in northern Indiana. The medium early varieties will doubtless mature in most parts of the state, and are to be preferred owing to their greater yield. The later varieties might be grown for soil renewal or soiling, but they would hardly mature seed.

Culture.—The soil may be prepared as for corn. If impoverished by previous cropping the soil should be well supplied with lime, potash and phosphoric acid. Nitrogenous manures have also proved beneficial in New England. The seed may be sown broadcast, with the wheat drill, in rows 16 to 24 inches apart, or with the corn drill to be cultivated as corn. The earlier varieties of soy bean may follow a crop of rye or barley, or be sown in the standing corn at the time of the last cultivation, if the weather is seasonable. If sown in corn put in two rows of soy beans between each two rows of corn. Sow about two pecks to the acre in rows, like corn, and cultivate, if seed is desired. For pasture, soiling or hay, sow four or five pecks to the acre.

Food Value.—Soy bean hay compares favorably with clover hay in chemical composition. The seed is very rich in protein and can therefore be fed advantageously with corn. The seed should be ground before feeding. The seed is readily eaten. Stock, as a rule, do not relish the stems and leaves at first, but soon take kindly to this forage. Soy beans and sorghum supplement each other as soiling crops. Corn and soy beans, together, are said to make good silage.

Harvesting.—Begin cutting at the time of early bloom, for soiling. Cut for hay when in full bloom, and as soon as the pods have formed, for silage.

Cost of Seed.—Seedsmen offer soy bean seed at $2.50 to $5 per bushel. This makes the cost far too great to justify growing soy beans as a general crop. Farmers are advised to try soy beans in a small way as a special crop, and then grow their own seed, if the crop gives promise of being valuable.

ILLINOIS TUBERCULIN TESTS.

A recent test of sixty-five cows at the Elgin, Ill., Insane Asylum disclosed the fact that twenty of them gave evidence of being affected more or less with tuberculosis.

Smiley and Clarke, of Kankakee, Ill., out of a herd of fifty-seven cows found eight infected. Mr. Smiley believes that their cows were all infected by one cow brought from Iowa. According to the Illinois law, cattle when tested and condemned are appraised according to their value and allowances are made to their owners according to the length of time the animals have had the disease. In no case will more than $75 be allowed a head. Grade cattle are appraised at $40 a head, thoroughbred Jerseys at $60, Holsteins at $75, bulls from $50 to $75.

Owners of cattle which have been diseased a year or less are compensated at the rate of 75 per cent of the appraised value of their stock. An allowance of 50 per cent is made on the appraised value of stock that has had the disease two years. When the disease has existed longer than two years no compensation is allowed. Full compensation is made for condemned cattle which show no traces of tuberculosis after an autopsy.

THE TUBERCULOSIS SCARE NOT FAVORED IN ILLINOIS.

The Governor of Illinois and certain of the boards of health in that state are doing what they can to injure the dairy and beef farmers and even had the effrontery to request the managers of farm institutes to cooperate with them, by requesting permission to send lecturers of their own choosing to institutes to talk on the dangers of tuberculosis. This request was respectfully and most properly denied and for the reason stated in the preamble to the resolutions adopted, which reads as follows:

The facts of human experience absolutely and undeniably disprove the statement that tuberculosis is a dangerously contagious disease, and the probability of the transmission of the disease from animals to man is yet disputed by eminent scientists; and the present unwise and unwarranted crusade of some representatives of the medical and veterinary professions against our herds, on the grounds of alleged disease, is prejudicing the public against beef and milk, the most wholesome of human foods, and thus working untold damage to agricultural interests.

"IT'S SCIENCE RUN MAD!"

They are having a "San José scale" war over in Canada, and the *Rural New-Yorker*, commenting on the report of a correspondent from that region, says:

From the notes given on page 495 about the treatment of scale-infested trees in the province of Ontario, it would seem that there is about as much of a craze there over the destruction of such trees as there has been in this country over the destruction of alleged tuberculous cattle. It's science run mad. This wholesale destruction of private property is little short of an outrage. There are some fruit trees, probably some orchards, likewise some cattle, that should be destroyed for the benefit of the public. But this wanton destruction when treatment would likely prove effective, is all wrong. Science should devote its energies more strongly to the saving of life and property, and not its destruction.

We wish it were true that the craze for the destruction of alleged tuberculous cattle in this country could be referred to as a "has been". While we may not be able instantly to stay the hand of the destroyer, we advise readers of HOARD'S DAIRYMAN not to lose their heads. Wisconsin is very likely to be called upon to pay full price for a valuable herd of dairy cows that were "condemned" by a state veterinarian. Tuberculin is all right in its proper place and purpose, but it is science run mad to kill every animal that reacts to the tuberculin test.

MILK Inspector Richardson, of Grand Rapids, Michigan, in a recent interview, shows how a great deal of trouble with milk and cream can be traced out, if only a fair, intelligent attempt is made. He says:

A city milk dealer who had paid a good price for a good route, was getting his milk from a farmer out near Cascade. Recently the milk has not been right, and the man found he was losing trade. He complained to the farmer, but the farmer could not find out what was the matter, and wanted to know as much as the dealer did. Consumers also complained. So I went out to Cascade, examined the pasture, the barn, saw the cows milked and got samples. I did not get back until late in the evening, but I told the farmer I suspected the trouble came from the milk of two cows, and suggested that he leave the milk from those cows out of what he furnished the dealer, and he was glad to act on the suggestion, until the tests could be made. This morning, while I was out on another matter, my assistant tested the milk, and established the truth of my suspicions.

Persons who have had any experience, whatever, in managing a creamery or cheese factory, know how often cases like the above arise. The Wisconsin Curd Test, invented by Prof. Farrington, is a great help in ferreting out the exact location of the trouble.

SAMPLE REPORTS BY A WISCONSIN DAIRYMEN'S ASSOCIATION CHEESE INSTRUCTOR.

The Wisconsin Dairymen's Association has, for years, had two or more cheese instructors in the field during the cheese making season. They go from factory to factory as they receive calls, but, as far as possible, endeavor to take them in succession in a district, so as to avoid loss of time and expense in extra traveling.

The instructors send to the secretary of the association, weekly, a full report of each factory visited. The first visit this year was made by Mr. E. L. Aderhold, of Neenah, to the factory of Peter Fassbinder, at Bungert, Outagamie County, April 26th to 29th. He gave this factory a second visit July 3d, and we give below the reports submitted to the secretary:

REPORT OF INSTRUCTOR FOR EACH FACTORY VISITED.

	First Visit.	Second Visit.
Name of Factory	Fassbinder	same
Name of Proprietor	Peter Fassbinder	same
P. O. Address	Bungert	same
Maker's name	H. Fassbinder	same
Has he attended Dairy School?	No	same
Wages (or price per pound)	1⅛ cents	same
No. of patrons	22	33
Pounds milk daily	3280	6905
Pounds cheese	294	686
Style of cheese made	Flats	Flats
Does maker "Guarantee his make"?	No	Yes
Does he stand the loss, if any?	No	No
What brands are used?	None	None
Steam or self-heating vats used	Steam	Steam
Is a curd mill used?	Yes	Yes
Curd sink	Racks	Racks
Is the whey drawn sweet?	Yes	Yes
Is the Babcock Test used?	Yes	Yes
Average per cent fat in milk	3.6	3.7
How are payments made?	Fat basis	Fat basis
How was the milk in the cans?	Good	Good
Was it properly aerated?	Yes	Mostly
How was the curing room?	Poor	Good
Can the temperature be controlled?	No	Yes
Give the temperature at time of visit	69°	68°
Were there screens to keep flies out?	Some	Yes
How far is whey tank from factory?	20 feet	20 feet
Is the whey scalded to 150 degrees?	No	No
How often is the tank cleaned out?	Occasionally	Occasionally
Any patrons watering or skimming?	No	No
Did you call an evening meeting?	Yes	No
How many patrons were present?	19	
Will you visit the factory again?	Yes	Perhaps
Give distance from last factory visited		65 miles
Give date of your arrival	April 26	July 3
And date of your departure	April 29	July 3
How much money did you receive?	$5.00	

Under the head of "Remarks" the instructor reports on his first visit as follows:

"There is much room here for improvement and a willingness by the owner to do so. I have persuaded him to ventilate his curing room from the bottom of a dug well, 90 feet from the factory. Air will be forced into the well with a wind cowl connected with top, and will be conducted from the bottom of the well by large metal pipes into two 10-inch tile ducts laid ten feet below the surface, leading to the curing room."

After the second visit made, as will be remembered, July 3d, he "remarks":

"A sub-earth duct has been built here this year. The air first passes into and through a well, thence nine feet below surface, to the curing room, a distance of ninety feet. It is giving excellent satisfaction. On this day the air entered the curing room at a temperature of 53°."

These reports indicate a most desirable combination of intelligent, appreciative patrons, who came out to attend the evening meeting on the occasion of the first visit, and a proprietor of a factory willing to adopt and make needed improvements in his plant. It is not so stated, but we presume the patrons assisted in putting in the sub-earth duct, at least to the extent of furnishing most of the labor needed in making the excavation.

We shall expect excellent reports from this factory in the future.

In contrast with the above, we give the "remarks," appended by instructor Baer, to reports of factories visited by him the latter part of June:

"Factory was dirty; maker lazy or careless. Cheese were huffed badly, flavor running sweet, cooked dry with no acid to break them down, curdy and of very uninviting appearance."

2. "This factory was very dirty and the goods showing up badly. Cheese was very soft, full of Swiss-holes, and growing off-flavor every day. Maker was slack in every detail of his work."

The Old Methods and the New.

(SYLVESTER BURCHARD in *Holstein-Friesian Register*.)

I have sometimes asked myself the question: Are the new methods, in every respect very much better than the old? In these days of sharp competition and restless strife, we cannot count much on the much-talked-of independence and undisturbed peace of the farmer.

I know a farm that, since my first remembrance, has been occupied successively by a father and his son, and I have had an opportunity, through a long series of years, to observe the methods of both. They were both frugal and industrious, and worked up to the opportunities of their time; but as I look over their career I cannot see that in prosperity or happiness, the son has exceeded the father.

The farm was purchased in 1838, and a heavy debt was incurred. In the month of March of that year, fifty cows were placed on the farm, without any shelter except an old rickety shed and a couple of straw stacks; these cows were all brought safely through to grass, although the months of March and April was the calving time of the season. In June, a barn, 36×80 feet, was erected and placed upon a stone basement, which was fitted up for a stable for the cows the next winter, the first cow stable worthy of the name in the neighborhood, and was thought, by many, to be a bill of useless expense. The next winter the cows had a comfortable stable, which they occupied in the night time, but it was not considered wise in those times to give cattle too much comfort, because it would cause them to become tender. Therefore, the rule was always followed (no matter what was the weather) of turning the cows out at nine in the morning, and putting them up at four in the afternoon. The cows were dried up in the early winter, and during the winter months were supposed to be recuperating, and getting ready for heavy work another season. In the spring-time they were allowed the run of the whole farm, and at times the boys were kept busy looking through the woods after cows that hid away to drop their calves. The tenth of May (a rule that was always strictly adhered to), the cows were always shut off the meadows and confined to the pastures, where they grazed until after haying, when again they had the run of the whole grass land of the farm.

There was no rotation of crops. The grass lands were permanent pastures and meadows, and the grain fields were constantly under the plow.

The haying season commenced about the middle of July, when extra men were employed, the force consisting of about seven men and two or three boys. The mornings were chiefly occupied in cutting down the grass, and the afternoons in getting it in the barns, this work being adjusted according to the weather and condition of the hay. I think many a modern farmer would be surprised, if he could have seen those bountiful crops of hay.

The next year another spacious barn was put up for the accommodation of the young stock and the horses. Those barns were always filled with hay, and many times numerous stacks were scattered over the meadows. The sod of the meadows was very compact, and the grass was a mixture of blue grass, clover and timothy, and when it rolled over from the scythes of the mowers, it had very much the appearance of a fleece of wool just taken from the back of a sheep, it was so fine and thick. It was considered excellent cow hay, but not so well relished by horses. A few acres of roots were grown and fed to the cows at calving time. The manure was wheeled from the stable and placed in a pile in the farther end of the barn. The teams were put at work early in the spring, hauling it on to the fields, so that it was all out before the field work commenced. What was made after that was piled up and hauled on the fields in the fall. The meadow land and the plowed fields received their due proportion of the manure, but much of this product had been wasted while the cows stood out in the winter days.

The milk from these cows was manufactured into cheese, and the product sold at from five to seven cents per pound, the whole make being sold and paid for in the fall, at which time the yearly supplies were purchased. Labor, it is true, was cheap, but on account of the absence of farm machinery and effective implements, twice the number of hands were employed, who had to be boarded as well.

This man occupied this farm fifteen years, until his death. In that time he had cleared a mortgage of four thousand dollars, and when his estate was settled, it was found he had a snug little bank account besides. His children were well educated and well dressed, and he stood in the community where he lived, as the respectable and successful farmer.

At the death of the father the son came into possession of the farm by buying out the heirs, which also brought upon him quite a debt. Very soon the spirit of progress stirred the heart of the young man, and the old farm became subject to many changes. The fertile and compact sodded meadows, that had lain so long undisturbed, were desecrated by the plow. Fields of corn occupied to a certain extent the place of the rich and luxuriant grasses. A system of rotation of crops was established, and in a few years

"Think of Ease But Work On."

If your blood is impure you cannot even "think of ease." The blood is the greatest sustainer of the body and when you make it pure by taking Hood's Sarsaparilla you have the perfect health in which even hard work becomes easy.

Hood's Sarsaparilla
Never Disappoints

Not a Preservative

but a preventive. If you would have your milk keep sweet longer and be free from all objectionable odors, use a CHAMPION Milk Cooler-Aerator. It does its work perfectly and it's use does'nt violate any law—it doesn't need to be used on the sly. Our book "Milk" is free.

CHAMPION MILK COOLER CO.,
67 Main Street, - Cortland, N. Y.

the original sod was all turned under. The barns were remodeled and out-buildings were erected. The cows were not allowed to graze upon the meadows, but were confined to the pastures, and a partial system of soiling was established. The stock had the best of care and never was allowed outside the stables in inclement weather. The boys missed the fun of hunting up the young calves, for they were all dropped in the stable. Absorbents were used in the stables, and every particle of the manure was saved; besides, a certain amount of fertilizers were purchased each year.

For a term of years the milk was carried to the cheese factory and the cheese was sold at very satisfactory prices. For about eight years the milk has been shipped to New York. The yield of milk per cow is a large increase over the olden time.

The new methods have been pretty thoroughly adopted by the son, and he is called an up-to-date farmer; but he will tell you to-day, if you will ask him, that the new methods have not given him more prosperity and happiness, nor a better standing in the community than the old methods gave the father. This object lesson does not prove that to get out of the old ruts always gives us a smoother road. I will not undertake to solve this problem because I could not if I would; but I hope some reader will see the efforts and results of these two lives in so clear a light that he will be willing to make it plain to us all.

Hamilton, New York.

HOARD'S DAIRYMAN will venture to express the opinion that the foregoing is in a large measure autobiographical, the writer of the article being the "son" referred to as succeeding to the business upon the decease of the original proprietor.

What is said about the "father" and his success as a dairyman farmer the editors of this paper can verify from personal knowledge, but they can hardly agree with the writer in his seeming disparagement of the new methods introduced by the son. It may be true, in a way, that they have not given him relatively more prosperity or happiness, or a better standing in the community than the old methods gave the father, but is it not equally true that if the old methods had been continued, the son would have fallen far below the standards reached by the father? Instead of being one of the leading citizens in the community where he has resided for more than sixty years as boy and man, the owner of the old homestead, out of debt, and with an income sufficient to meet every demand and surround himself and family with all modern comforts and conveniences, as well as follow the father's footsteps in the paths of benevolence and charity, he might have been, as so many others in that county have become, living in a restricted way, harrassed by debts, and obliged to forego much that he now considers essential to his happiness and independence.

It should not be forgotten that the father had a virgin soil, and that methods which then produced those fleece-like swaths, would give but beggarly returns now. The father was all right in his day both in his farming methods and in the scale of his expenditures for himself, his family and for public, charitable and benevolent purposes, but as times change it becomes us to change with them.

Cedar Hill Dairy Notes by Buff Jersey.

Flies—Feeding—Chickens.

ED. HOARD'S DAIRYMAN:—Thanks for answers for inquiry regarding power for our ensilage cutter. If every dairyman in our country knew the value of a wide circulating journal like the DAIRYMAN how much less complaint would be heard regarding dairy and herd management.

My query was answered at once by men who could speak from actual experience. Their answer enables us to go ahead and do the work that otherwise would have to be done experimentally and in the event of a mistake would cost us many times what our paper costs us annually.

Yesterday the milk agent of one of the leading rail-roads running into Chicago visited us. We called his attention to our herd's being free from flies, and to our daily milk record, showing herd gaining daily. He reported that on his road the milk shipments had shrunk fully 100 cans in 300, or ⅓, and that it was the case every year in fly time.

With us the comfort of milking quiet cows repays us for the expense and trouble of applying Shoo Fly.

How many of the DAIRYMAN readers have suitable instruments, etc., in milk stables. We have in our stable a box that at all times contains several lengths of milk tubes, an instrument for opening obstructed teats, a bottle of liniment for caked udder, a bottle of creolin, or other good antiseptic preparation, (we like creolin the best,) but in no corner or place do you find in our stable any lotion or preparation for milk fever. We never have a case of it. I often wonder at its prevalence, and why we cannot have our share of it. In past fifteen days of hot weather we had seven cows freshen, and not one of them missed a feed and all doing finely at the pail. I never saw but three cases of milk fever in my life, one in Wisconsin, one in Missouri, and one in Colorado.

Our 2-year-old heifer we reported last spring making fifteen pounds of butter in one week, has produced 2 pounds of butter daily since March 2nd, and is to-day yielding finely. Another 2-year-old weighing 470 pounds is giving daily 21 and 22 pounds of milk.

Pastures are good with us, but for all of that our best cows get daily 8 pounds of mill stuff, corn meal, brewers grains (dried) and cotton seed meal. It pays to feed cows every day of the year. We know this from years of actual experience; our daily milk records will prove it to any one.

Our two incubators are to-day turning out chickens of four breeds, namely: S. C. B. Leghorns, White Leghorns, White and Barred Plymouth Rocks. In filling them we had to buy eggs, hence the variety. Some came from Quincy, some from Gurlaw, and some from our own neighborhood. We have chickens now seven weeks old that pull our scales down to thirty-one ounces. We will cut down our number of hogs and feed our skim milk to poultry, it will pay better, we think. We are of the same opinion of our friend, Gurler, of DeKalb, that hogs are a nuisance around a creamery and herd.

"BUFF JERSEY".

Dilution Separator Sharks.

ED. HOARD'S DAIRYMAN:—I saw in your paper of June 30th, an account of a test of the "hydraulic separator" in Iowa. I see by that, all the smart men do not live in our Allegany County. There have been a number of these so-called separators sold in this county, and last week there was a man came, and took the deputy sheriff and went to these parties, and asked royaity for using them. Some of them paid, but did not get so much as a receipt for their money, but he had them sign a paper agreeing not to swear against him in any court. Others would not pay. Do not know what will be done next.

It seems strange that farmers will be so humbugged. There has been more than twenty thousand dollars taken out of two or three towns in Allegany County, and still they come. Farmers complain of hard times, and then buy trash of every shark that comes along. J. C.

Andover, N. Y.

This is by no means the first report which the DAIRYMAN has received, of farmers being victimized in the above manner.

It is the legitimate outcome of some of the methods which have been used in introducing the so-called "dilution separator." There is so little difference in the patents granted on these machines, that no dairyman who buys one is safe from a demand for royalty from competing manufacturers.

It is much easier to go to the farmer and demand five dollars for the use of an alleged infringement on a machine, than it is to bring an expensive suit against a strong competitor. The result is, that the farmer is fleeced on both sides, both in buying the machine, and after it is bought. It is time that this subject was ventilated in a thorough manner, and we should be obliged, if our correspondents would keep us informed of cases like that given in the above letter, where the farmers have been systematically defrauded of their money.

HOARD'S DAIRYMAN hopes that none of its readers have been victimized, for it has done what it could to protect them, by stating over and over again, first, that the process itself was no improvement on other methods of cream raising, and, second, that if anyone wanted to try it, any common, deep setting can or pail was just as good, as any of the high-priced, patented affairs.

More than this, although frequently solicited to accept advertisements for these so-called separators, this paper has persistently refused to give space, at any price, for that purpose. This means, of course, hundreds of dollars of direct loss to us, but we hope it has been made up many fold, to our readers.

A Good Wisconsin Herd Record.

ED. HOARD'S DAIRYMAN:—I will do as I promised some time ago, and tell what I received per cow, each year, counting calves and milk that I sold, not including what was used in the house, nor in any other way. I began selling milk May 1, 1895; year ending April 30.

In 1896, six cows averaged	$45.59
In 1896-97, eight cows averaged	44.42
In 1897-98, ten cows averaged	52.69
In 1898-99, thirteen cows averaged	66.52

In the year 1897-98, the ten cows gave 62,340 pounds of milk, or an average of 6,234 pounds, that is, I sold 62,340 pounds from the ten cows, and I fed ten calves; sold six of them, and raised four. Those six sold at an average of $6.68. They were the poorest calves I have had since I have been dairying, and I count the four I raised at the same price.

This last year I sold eleven calves and raised two. The eleven averaged $10.35. I also count those two at the same as the eleven averaged. It takes more whole milk to raise a calf than it does to veal one.

I feed those I raise whole milk, water and oil meal. I sold 96,121 pounds of milk which gives an average of 7,317 pounds.

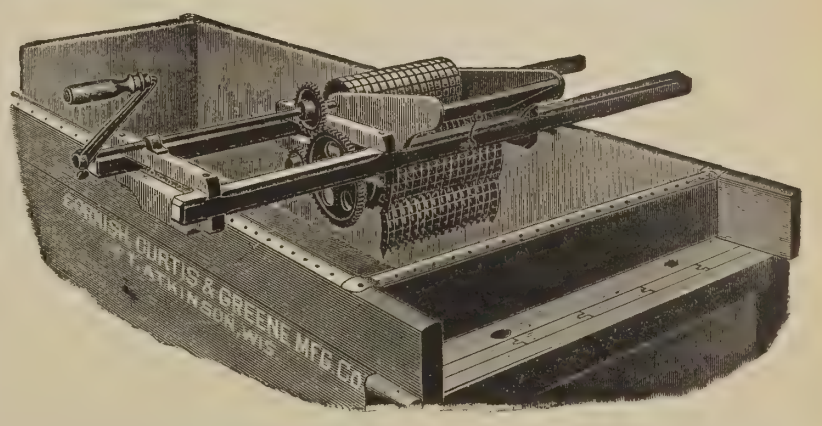
Now about their age: One calved at eighteen months, two at two years, two at three years, one at four years, six from six years old to nine years, one at sixteen years.

Their feed was grass in the summer, 5½ months, and I fed them 6½ months. Their dry feed was marsh hay, corn stalks for roughage, bran, corn meal, corn and cob meal, a little oil meal, and a little gluten feed, seventy bushels ground oats. It costs $33 per cow, for board, for the year. I count only what was fed to them; don't count work or stable room, simply the food eaten.

Whole amount of milk taken from the thirteen cows, 103,121 pounds; total amount of money received, $851.81.

Now, I don't think it is all in the cows or in the breed; it is just as much in the care, and they want a good balanced ration. They want plenty of it and want it regular and also want to be milked regularly. There are men taking milk to the same factory that I do that say it don't pay to feed cows. I claim it don't pay them the way they feed. There are thirty-nine patrons at our factory, and I am the only one that has a thorough-bred bull at the head of the herd. I don't think I would have received what I did only for the help I received through the DAIRYMAN. Some people don't like it. You can judge why. A SUBSCRIBER.

Fond du Lac Co., Wisconsin.



Millet for a Catch Crop.

Many of our readers, no doubt, are looking for some forage crop to sow the present month, and a few words on millet will be in order. For the purpose of forage it is still time to sow a crop of German millet, if the ground can be got in good condition We have had so little rain in Central Indiana that it is almost impossible to put the soil in fit shape for seeding. Millet wants good, mellow soil, with more loam than clay. The seeds are small and it must be well pulverized to make them germinate. With the soil well prepared and the seed properly put in, the plants grow very rapidly in the mid-summer months. A sprinkling of barnyard manure over the surface will help very much in giving it a good start. If the ground is reasonably mellow it may be put in with a disc harrow. The amount of seed varies with the quality of the soil. If rich and in good tilth, half a bushel to the acre is sufficient, but if the soil is thin and cloddy twice the amount will be none too much.

The hay should be cut before the seed begins to harden. Sown as late as this it may have to be cut when first in bloom, or even sooner, to escape frost. To those who have not tried it the yield of hay will be a surprise, in good soil As to the value of hay and the danger from its constant use, we quote from an article on the subject in the Year Book of the U. S. Agricultural Department for 1898: "Millet is fed principally as a hay and soiling crop. As will be seen from the chemical analysis, the forage ranks well with that of other grasses in the nutritive content, and its palatability is about that of the average for the coarser sorts. For digestibility, millet compares favorably with that from other coarse grasses. Already widely grown as a hay crop, millets deserve more general use for soiling. They are particularly valuable for feeding to dairy cattle, young stock and sheep.

"Millet at any stage of its growth acts as a laxative and diuretic. At times the action is more pronounced than at others; thus, hay cut while the plants are quite young seems to be most strongly laxative, while over-ripe hay is most strongly diuretic. However, if the hay is cut at the right stage of growth and properly cured, the action in either case will not be sufficient to lead to serious results if other hay or coarse forage is fed along with the millet. One feed of millet hay per day for work horses and one or two for other stock is sufficient, and when fed in this manner the millet acts as a stimulent and alterative, and tends to produce and maintain a healthy condition of the animals."—*Ex.*

Kasper Rotary Curd Mill.

The demand for a large capacity curd mill for cutting curd into cubes has induced the inventor to bring out the Kasper Mill. In construction the mill consists of a rotary cylinder made of knives in the form of cubes. Against these knives a wooden roll revolves with indentation to fit the knives of the cylinder; the curd being fed into the hopper is forced through the openings in the cylinder by the wooden roll. The cylinder is made in three sections hung on hinges, and, as it revolves, each section as it comes to the lower part of the cylinder, opens and allows the curd to drop into the vat, the section closing again as the cylinder revolves.

It is estimated that the curd from 7,000 lbs. of milk can be cut in from 7 to 10 minutes. The mill operates easily, being light-running and adjustable to either hand or belt power. Simplicity of construction, durability and ease of cleaning are some of its principal features. All parts being galvanized or tinned prevents rusting. Weight of the machine complete is about 38 pounds. List price, **$25.00**

CORNISH, CURTIS & GREENE MFG. CO., Fort Atkinson, Wis.

Inventors, Manufacturers and Dealers in Everything Pertaining to Butter and Cheese Making.

Agents for DE LAVAL ALPHA SEPARATORS.

BREAKING THE LAW.

From a circular advertising the merits of a new milk preservative, we find that milkmen, in the following towns, are using the preparation, and do not hesitate to allow the fact to be known. What are the officials in the various towns doing to prevent it? Following is the list:

Dayton, Ohio.
Dean, Ohio.
Defiance, Ohio.
Mummaville, Ohio.
National Military Home, Ohio.
Gibsonburg, Ohio.
Miamisburg, Ohio.
Trotwood, Ohio.
Elkhart, Indiana.
Selin's Grove, Pennsylvania.
Williamson, New York.
Peoria, Illinois.
Chittenango, New York.

The dealer in Trotwood, states that his milk has been tested four times while using ——, and was never detected. This speaks well for the analyst.

Butter-Milk From Skim Milk.—The Average Cow.

ED. HOARD'S DAIRYMAN:—Can you tell me how to make good, palatable buttermilk from skim milk? We can not sell our buttermilk, because it is too rancid to taste good, and, in fact, I never saw the buttermilk any other way when made from ripened cream.

I have been reading the DAIRYMAN for over two years, and I have never seen a profit figured for the creamery patron. The men that publish good profits from the dairy business, have not been creamery patrons. The average cow makes 200 pounds of butter in a year; figuring this at twenty cents gross, or seventeen cents net, is $34. The cost of feed is $30, and the other $4.00 pays the interest on the investment. Taking care of this cow is worth $15 more, while the skim milk is probably worth $8.00, if figured at twenty cents a hundred. Where is the profit? F. Z.

Kirksville, Mo.

Ripen the skim milk with the same care you would your cream, and churn when the skim milk has just loppered.

If you wait till the skim milk has taken on more acid, the casein will form tough lumps instead of a smooth, fine mixture in the churn. Any flavor of rancidity in buttermilk is a sign of improper ripening.

The profits of creamery patrons have been discussed many times in the DAIRYMAN, and our correspondent will find on page 451 of the present issue, an excellent account of a successful creamery patron.

It is true that the average cow gives but 200 pounds of butter per year. But may we ask why keep a cow that only gives that amount? The DAIRYMAN has constantly advocated the necessity of the average dairyman being more than average, and keeping more than average cows. The average cow is the curse of the dairyman; she costs just as much, if not more, for maintenance, as one of better quality. The butter she gives costs more to produce, takes more food, and her calf is of less value. Why then should the dairyman persist in breeding and keeping her?

The three hundred pound cow costs no more to breed and raise, than her two hundred pound sister. She will produce more butter, at a less cost, be of more value herself, and her calves will also be worth more.

A man cannot expect to succeed if his tools are old and poor. Keeping an average cow is like reaping grain with a sickle; in both cases the expenses eat up the profit.

A Lease of Fifty Cows for Six Years—The Owner to Receive Only the Increase and the Manure.

I have leased fifty graded cows for six years and have agreed to give to the owner all the increase in cattle and the manure for the use of cattle, corn, dairy room, one horse and wagon, separator and all necessary fixtures for running a dairy in a town of 12,000 inhabitants. I have agreed to let the increase stay in the herd, with the owner of the herd exchanging bull calves for heifer calves I can get good pasture for 50 cents per month per head, and sell all the milk for 20 cents per gallon and butter at 20 cents per pound.

Who has the best of the trade? I have also agreed to deposit on Saturday of each week, for six years, seven dollars as collateral security that I will carry out my part of contract.

I am to feed calves a sufficient amount of skim milk to keep them in good growing condition. What amount of skim milk would you say would be sufficient for calves, and how long would you say it would be necessary to feed them on skim milk? And what will be the best feed for calves after leaving off the milk?

I read your paper and find many things of interest to a new man in the dairy business.

Greenville, S. C. S. A.

We suspect that neither party to this lease realizes the astounding results of a geometrical ratio. If it is assumed that only one-half of these cows and the increase when the heifers come to two years of age produce living, healthy calves, the herd will number 350 animals at the end of the sixth year, and nearly or quite 190 of them will be giving milk.

This will be a pretty large business to handle, requiring very considerable capital and a small army of help. If it was not for its magnitude, the terms of the lease are favorable enough.

The calves should have new (whole) milk for the first ten days, 10 to 15 pounds, and be gradually weaned from that to skim milk, taking a period of at least 10 days to make the change complete. The skim milk should always be warm and by this we mean between 95° and 100°. The amount should range between 15 and 20 pounds for the first five weeks, and never exceed 25 pounds per day. Bran, whole oats, or barley, or a little ground flax seed, may be fed in connection with the skim milk, but never any cotton seed meal. As soon as the calves will nibble at hay, usually before they are four weeks old, they should have a little first quality hay, and fresh every day. Calves may be weaned from milk at six months of age and thereafter should have the best of forage and grain sufficient to keep them thriving, but not fat.

As to Durham (Short-horn) Cattle.

ED. HOARD'S DAIRYMAN:—I have been watching for something in the DAIRYMAN in regard to Durham cattle, but see nothing. Why is it? Are they not worthy of mention in your valuable paper?

I have a number of cows of no particular breed, which are giving me about one pound of butter per cow per day. I use a separator so I think I get it all; should I be satisfied?

Now, to be brief, I have plenty of rough pasture land, but it is four miles from where I live, and the land where I live is the finest farm land to be had, with every acre tillable, and I think I could raise some good breed of cattle and keep a small pasture here at home for milk cows, and pasture all young stock and dry cows off on the rough land which is good for pasture only, giving me most of my good land to raise feed for winter.

There are quite a number of Durham cattle around here (no Holsteins) and I have been wondering whether they were my cattle or whether Holsteins would be better.

Some people tell me that Durham cows give rich milk, but little of it. What do you think?

Again, others say that Holstein cows give great quantities of milk with very little fat in it. Is this true?

Others say that Jerseys give lots of butter, but the steers and old or poor cows are worth but little to turn off.

Now, you see, with 80 acres good farm land, and 100 of good pasture, (4 miles off) I can feed quite a number of cattle, winter and summer, and if you can give me any information, it would be gratefully received.

I am intending getting a good bull of my own after I have decided what I want.

Baraboo, Wis. A. D. H.

HOARD'S DAIRYMAN makes but little mention of Short-horn cattle, for the reason that it is distinctively a dairy paper, and that breed of cattle, as it exists today, is not a profitable breed for dairymen. There are in the aggregate, a large number of excellent cows among pure bred Short-horns and grades of that breed, but they really constitute but an insignificant minority as compared with those that are not good cows, and these cows have been bred so persistently in beef lines that there is but little probability of their progeny inheriting dairy ability. We have no purpose in this reply of re-opening the question as to the possibility of developing a breed or strain of dual-purpose cattle, by continuous selection and careful breeding. It suffices to say that such a breed or strain does not now exist, at least on this continent.

It should not be forgotten that it does not necessarily follow, because a cow produces a large quantity of milk or butter in twelve months, that she is a good cow. Economy of production, as was pointed out by Prof. Haecker last week, is equally as important as amount of production.

In the Ninety-day Butter Test at the World's Fair in 1893—twenty-five selected cows from each breed competing—the food cost (at the prices then charged for feed) of producing a pound of butter fat was 16.7 cents for the Jerseys, 17.3 cents for the Guernseys and 20.7 cents for the Short-horns, or in the proportion of 100, 103.6 and 123.9 respectively.

In view of all the facts, we do not hesitate to advise A. D. H. to confine himself to dairy bred cattle for his milking herd, and if he wishes to stock that rough pasture land with young steers for beef, buy some of the calves or yearlings from the neighbors who keep "Durhams" (Short-horns).

We cannot decide for him whether he shall choose Jerseys, Guernseys or Holsteins for his dairy. He can buy a good bull of either breed to cross on the cows he now has, and raise a herd of grades that will bring both profit and pleasure in dairying. The better the bull, the more valuable will be his progeny. See to it that his dam and grandams were cows of good breeding and good producers. And in the choice of a breed, follow personal inclination.

Some Danish Dairy Laws.

The *Smor Tidende*, of Denmark, takes up the matter of cleanliness in Danish dairies, and quotes the law on "Measures for the Prevention of Tuberculosis in Cattle," passed something over a year ago, the last provisions of which will go into effect June 1st next. Sections of the bill read as follows:

"Cows suffering form tuberculos is in the udder shall be killed under official control, either in the presence of the veterinary police, or in the public slaughter houses (the government compensating the loss to the owner.) * * * The dairies are prohibited to give off milk or buttermilk for cattle food, unless such milk has been heated to a temperature of at least 68° R. (185° F.)

"When cleaning a separator, the mud on its wall shall be burned. * * * importation of milk and buttermilk to this country is only admitted on condition that it is proved to the satisfaction of the minister of agricultural, that it has been heated to a temperature of at least 68° R." (185° F.)

"These enactments will have the effect of making the pasteurizing of all milk in Denmark compulsory, as otherwise the farmers cannot get back their skim milk from the dairies, to feed to their calves and pigs. In no other country has been done so much to prevent tuberculosis in cattle, or the spread of infectious disease in man, as in Denmark, and, as a consequence, the state of sanitary matters in Denmark is generally very satisfactory."

Instead of a general slaughter of cows that react to the tuberculin test, it would be better to look after the sanitary condition of drains and cow stables. Tuberculous cows are a result not a cause, and will continue to be produced as a consequence of unsanitary surroundings.

Killing the animal after it has taken the disease, will not prevent another generation of tuberculous cows, unless, at the same time, sanitary rules and regulations are made and enforced.

Denmark is following this road, and it will not be long before the results will be seen in the quality of her dairy goods, and health of her live stock. This country will probably move in the same direction, but not till the politicians, veterinarians and doctors have finished their present senseless slaughter of dairy stock and have devoted their energies to a systematic enforcement of sanitary rules and regulations.

Fall Grains

need a good start to stand the winter; therfore feed them well in the beginning. This will produce hardy plants with plump grain. A good fertilizer should contain plenty of

Potash

Potash increases stiffness of stalk and plumpness of grain.

GERMAN KALI WORKS,
93 Nassau Street, New York.

Success to the Man Who Reads and Thinks.

HOARD'S DAIRYMAN is not the only advocate of reading and thinking for dairy farmers, and that its advice in this respect is not founded upon selfish motives is sufficiently demonstrated by the following article from Prof. D. H. Otis, in the *Kansas Farmer*:

Among the questions asked of creamery patrons by the Kansas Experiment Station is, "What dairy or farm paper do you read?" Out of 77 patrons who answered this question we obtained the following record: *Kansas Farmer*, 5; *Orange Judd Farmer*, 5; *Live Stock Indicator*, 4; *Philadelphia Farm Journal*, 3; *American Agriculturist*, 2; HOARD'S DAIRYMAN, 1; *Farm and Home*, 1; *Farm and Fireside*, 1; *Agricultural Epitomist*, 1, and *Drover's Telegram*, 1. There were 53, or 69 per cent, of the patrons who reported that they read no dairy or farm paper.

In looking over the details of the above records it is interesting to note that the best records were made by those who kept posted and studied their business. The highest yield was made by a man who keeps special dairy cows and subscribes for a DAIRY paper. This patron realized $9 per cow per annum more than the next best patron who reads no paper, and $36 per cow more than the poorest patron.

Because a man subscribes for a farm paper is no guarantee that his cows will yield large quantities of milk, but it has a strong tendency in that direction. No doctor could expect to succeed without keeping himself posted along the line of his profession. It is true that experience is the best teacher, but the tuition is high, and no man can expect to accumulate even a small fraction of the world's experience through his own unaided efforts. If he is to keep himself posted he must learn by the experience of others, and how can he do this except he reads literature pertaining to his profession? Nowhere is intelligence needed more, and never can it be applied to better advantage, than in dairy farming. In collecting records from various parts of the state we find that where intelligence is applied to the dairy industry the cow is yielding from $60 to $80 in dairy products per annum. Contrast this with $20 to $30 without intelligence, and no one need ask if education pays. At the Kansas Experiment Station we find that intelligence applied to feeding will cause calves to gain from 12 to 23 pounds per week instead of 7 to 10 pounds. The man who never reads a farm paper will know nothing about these facts. He will still continue in the old rut, and say he doesn't believe in book farming; that education will not help the farmer; that

the men who write for papers know nothing about farming. Some day these men will wake up, feel of their pocketbooks and find that they are behind the times. Sixty-nine per cent of the dairy farmers without a farm paper! No. wonder so many Kansas cows produce under 125 pounds of butter per annum; no wonder there are so many complaints about sour milk and about poor calves raised on skim milk! This is an age when intelligence can be turned into cash; when, as Secretary Coburn says, "Muscle, to win, must be lubricated with brains."

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—The offerings of butter on the Board of Trade amounted to 29,460 pounds to-day. There was little activity in bidding, and but four lots sold, as but 17 cents was offered.

The following sales were made:

Factory.	*Pounds.*	*Price*
Winslow	1,560	17c.
Shannon	960	17c.
Baileyville	1,440	17c.
Cobb	1,800	17c.
Total	5,760	

Former markets:

July 18, '98, 7,620 lbs. at 16½ cts.
July 19, '97, 20,700 lbs. at 14½ cts.
July 20, '96, 40,620 lbs. at 14½@15 cts.

Elgin, Ill., July 17. H. C. B.

Regularity in Milking.

In the management of a dairy, regularity in milking is of the highest importance. The easiest way, says an exchange, to make cows uncertain, in their milk yield, is to milk anywhere from 5 to 8 o'clock in the morning, with a corresponding latitude in regard to evening milking time. Most dairymen understand this, and take measures to have the milking done at the same time each day. Unfortunately, however, in many herds, Sunday comes in as a disturbing element. It is a day of rest, and those who do the milking are less prompt and less regular in their work, than on week days. The result is, that it is often well toward the middle of the week, before the evil effects of Sunday's irregularities disappear, and then they reappear again in the early days of the following week. The effect produced is not only harmful during the days of actual disturbance, but it is believed to exert a bad influence on the work of the cow during the entire period of lactation, the evil becoming gradually and increasingly more prominent, and finally closing the milking period earlier than it would have closed, had the milking been regularly done every day in the week at the same hours. This is one of the points at which dairying is exacting. Things must be done, milking included, on time, and this is one reason why so many people think that dairying is a very troublesome occupation. In some respects, this is true, but one of the compensations for this is, that farmers are more prosperous in the dairying districts than others, wherein other branches of farm work are relied on. It is quite true that the dairy farmer has to get up very early to attend to the milking, and that he has to do it every day in the year, but on the other hand he is in less danger of having to lay awake at night worrying his brain in a struggle with the problem, where the money is going to come from to pay taxes and other necessary expenses.—*The Dairy Reporter.*

Increasing the Profits.

The Meriden Creamery company of Meriden, Kan., find that their patrons, who know how to feed, get from $40 to $55 income per year from each cow, while the patrons who do not know how to feed get from $18 to $25 per cow per year, and that the net profits received from each cow by their best patrons are 11 times those received per cow by their poorest, writes Mr. H. M. Cottrell. They also find that some of their patrons get no profit whatever from the skim milk, while others who know how to feed it get from 25 to 50 cents from each 100 pounds of skim milk fed. As there are 5,000 pounds of skim milk from each good cow yearly the way it is handled makes a great difference in the profits from dairying. The Meriden company believe that if their employees are thoroughly instructed in these lines of feeding they can help the farmers who sell milk to the creamery to largely increase the farmer's profits and at the same time increase the profits of the creamery. For this reason the stockholders of the Meriden company have decided to send all their employees to the Kansas Dairy School at Manhattan and require them while there to make a special study of feeding dairy cows and of feeding skim milk to calves and hogs.

The above contains the essence of what HOARD'S DAIRYMAN has been trying to inculcate for years. It certainly does pay a handsome profit to study and know all we can on this question of dairy feeding.

DAIRY MARKETS.

ELGIN, Ill., July 18—Five hundred tubs butter offered; 96 sold 17c. Quotation committee reported official market steady at 18c.

CHICAGO, Ill., July 17—Eggs fresh, at mark, cases returned, sold at 11c; loss off, cases returned, 12c.

Cheese—Full cream, twins, new, good to choice 8½@8¾c; young America, 8¾@9c; Swiss, 12@13½c; Limburger, 7@8c; Bricks, 7@8½c.

Butter—Creamery, extra, 17@17½c; firsts, creameries, 15½@16c; seconds. 14@ 5c; dairies, selections, 15@15½c; No. 1 14c; No. 2 13c; extra ladles, 12½@13c; packing stock, fresh, 12c.

Bran—In fair demand and prices firm at 11.85 @12 per ton.

Cattle—As the supply of cattle was not excessive to-day, prices were fairly steady for good cattle. Good to fancy steers brought 5.25@5.85; commoner grades 4.85@5.20; stockers and feeders 3.50@4 85; bulls, cows and heifers 2.00@5.10; Texas steers 3.50@5.25; calves, 4.50@6.75.

MILWAUKEE, Wis. July 17—Butter—Fancy prints per lb 17½c; extras per lb, 17½c; firsts per lb, 16½c; seconds per lb, 14@15c; Imitations per lb, 14@15c. Dairy—Selections per lb, 14@15c. Lines per lb, 12½@13; packing stock 11@11½c. Market unchanged; receipts 20,250 lbs; trade fair, chiefly for cheaper qualities.

Cheese—American full cream—New, choice to fancy 8½@9½c. Brick—New per lb, choice 7¾@8c. Limburger—New, choice per lb, 8@8½c. Swiss—Drum, choice, 12½@13c; new block, choice 10@10½c.

Eggs—Fresh per doz. 12c loss off cases returned

SHEBOYGAN, Wis., July 12.—Cheese—Was in good demand on the dairy board at this city to-day. The sales were 1,000 Young Americas at 8⅝c and 500 Twins at 8½c.

MANITOWOC, Wis., July 12.—Offerings of cheese at the dairy board to-day were: 800 boxes Daisies, 100 boxes Twins, 800 boxes Young Americas. All offerings sold at 8¼ cents.

SHEBOYGAN FALLS, Wis., July 12.—Sixteen factories offered 1,290 boxes of cheese on the Call board and all but two lots were sold as follows: 725 cases Young Americas at 8¾ cents; 145 at 8⅝ cents; 156 boxes Twins at 8⅝ cents, and 150 Daisies at 9⅛ cents.

APPLETON, Wis., July 15.—The offerings on the Outagamie County Dairy Board of Trade were Cheddars, 440; Twins, 1,068. The sales were 326 Cheddars at 8⅝c; 226 Twins at 8¾c; 500 Twins at 8⅝c.

BERLIN, Wis., July 15.—The offerings on the Dairy Board to-day were 341 Twins and 22 Cheddars. All sold at 8½c.

BRILLION, Wis., July 14.—Sales of cheese on the Brillion Dairy Board, 379 Young Americas, 8⅝c; 877 Twins. 8¾c; 992 Daisies, 8¾c.

AVOCA, Wis., July 17.—On the Lone Rock and Muscoda Dairy board to-day offerings were 1,375 colored twins, 230 white twins. Market firm and all sold at 8½ cents.

FOND DU LAC, Wis., July 17.—Offerings 678 twins, with active market at 8⅝ cents.

ST. LOUIS, Mo., July 17—Butter—Quiet; creamery, 14@18½c; dairy, 12@15c.

Eggs—Steady at 9½c.

PHILADELPHIA, Pa. July 17—Butter—Solid packed: Separator creamery, extra, 19c; creamery firsts, 18c; seconds, 16@17c; imitation creamery, extra, 16c; firsts, 15c; seconds, 13c. Ladle-packed: Extra, 14@14½c; firsts, 13½c; seconds, 13c. Print butter: Creamery, extra, 21c; firsts, 20c; seconds, 18@19c.

Eggs—Pennsylvania and near by, 13c; Western, 13@13½c; Southwestern, 13c; Southern, 10@11c.

BALTIMORE, Md. July 17—Butter—Market steady. Creamery, separator, extra, 20c; extra, first, 18@19c; creamery, first, 17@18c; creamer, imitation, extra, 15@16c; ladle, extra, 14@15c: Western store packed, 11½@12½c.

CINCINNATI, Ohio, July 17—Butter quiet. Eggs 9@9½. Cheese in good demand; good to prime Ohio flat 8@12.

NEW YORK, July 17—Butter—Receipts 15,578 pkgs; irregular; Western creamery 15@18½c; factory 12@14¼c. Cheese—Receipts 8,799 pkgs; firm; large white 8½c; small white 8½@8⅝c; large colored 8½c; small colored 8½@8¾c. Eggs—Receipts 11,820 pkgs; firm; Western 14½@15c.

BALTIMORE MARKET.

BALTIMORE, July 13.—Butter—Despite the summer heat, and the exodus of people so circumstanced that they can "ex" whenever they are driven or inclined, and the falling off in consumption of fine separator creamery consequent thereupon, the market has generally born a brisk appearance. The receipts of separators have been of liberal volume, and the grading very good, and whatever could not be sold went into the freezers with every promise of safe carriage and reappearance upon the market at some future time to supplement short current supplies. The gathered cream products, however, though in limited receipt, appeared to be unfavorably affected by the weather to a greater degree; and even among the regular and favorite marks, such summer defects as "acidity," and the indescribable flavors usually met with about the dog days, and known by the seasonable term "summery." have made their appearance to such an extent as somewhat to interfere with the course of trading and prices. "What is one man's food is another man's poison," the higher prices hindering sales of extra separators help up the quality of the gathered creams. There has been a further falling off in the receipts of imitation creamery and ladle packs of present makes, which materially curtails the business done with nearby cities and towns as they have been limiting their purchases of late to these varieties. Receipts for storepacked have been very light, with the demand active for all grades

Creamery separator, extras 19c; firsts 18c; seconds 17c; gathered cream, extras 18c; firsts 17c; seconds 16c; Ohio, extras 18c; firsts 17c; seconds 16c; Ohio Storepacked 12½@13c; firsts 12c; W. Va., extras 12½@13c; firsts 12c: Creamery blocks (2 lb.) extras 21c; firsts 20c; seconds 19c; prints (½ lb.), extra 21c; firsts 20c; seconds 19c; Md., Va., & Penna prints, extras 19c; firsts 18c; seconds 16 @17c.

Eggs—Have been in quite liberal supply of the kind. There is some accumulation of heated and other faulty stock. The only kind that is wanted are choice fresh eggs; this kind will always sell at a price. We urge you to be very careful what kind of eggs you ship, and how you pack and ship same. Market steady on all choice to fancy eggs at 11½@12c.

Cheese—The receipts of cheese are ample. Trade fair for season. Market steady, N. Y. State Cheddars fine 8¾@9c; choice 8¼c; fair 8@8¼c; Flats, fine 9@9¼; choice 8½@8¾c; fair 8¼c; Small, fine 9¼c, choice 9c; fair 8¼c; Ohio flats 8½@8¾c; choice 8@8¼c; fair 7¼@8c; Picnic, fine 9@9¼c; choice 8½@8¾c; fair 8¼@8½c; Swiss cheese fine 13½@14c; choice 12@13c; fair 11c.

NEW YORK MARKET.

NEW YORK, July 15—Butter—Receipts for the week, 56,635 packages. Exports for the week, 3,484 packages.

The market is demoralized and prices are decidedly lower to do any business. Receipts continue heavy and receivers have grown tired of putting butter into refrigerators at 1@2c pound more than its real value; the only good thing to report is the appearance of exporters in the market as buyers of good to fine makes. Creamery butter at 16@17c, and sale is reported of 500 tubs fine quality at 17¼@17½c. Finest trade is taking sparingly of extra creamery at 18¼@18½c, but there is so little of this kind of business that it is hardly quotable. At the close there are free offerings of all grades of butter and buyers are having their own way, and sales for export are at 16@17c for creamery and some purchases for eastern and speculative accounts at 17@17½c. We quote:

Creamery, extra, 18c; medium, 16½@17½c; poor, 15@16c. Dairy, extra, 17@17½c; medium, 16@16½c; poor, 14@15c. Ladle, 14@14½c; medium, 13½@13¾c; poor, 12½@13c.

Cheese—Receipts for the week, 38,783 boxes. Exports for the week, 13,841 boxes.

This market is just the opposite of butter. Every one seems to want cheese and there is not enough arriving to go around, prices are higher and firm. Sales of Western N. Y. cheese at Cattaraugus yesterday at 8⅜@8⅞c. We quote:

Full Cream, large, extra, 8½c; medium, 8@8¼c; poor, 6@7½c. Full Cream, small, extra, 8¾c; medium, 8@8½c; poor, 6½@7½c. Part Skimmed, extra, 7¾@8c; medium, 7@7½c; poor, 5@6c. Skimmed, poor, 4@5c.

Eggs—Receipts for the week, 55,866 cases. The demand is only for strictly fine fresh laid stock; other grades are abundant and prices nominal. We quote:

N. Y. & Pennsylvania, finest marks, per dozen, 15@15½c. Northern & Western, finest marks, per dozen, 14½@15c. Other grades, per dozen, 12@14c. DAVID W. LEWIS & Co.

177 Chambers St.

FOREIGN MARKET.

BOSTON, July 15—Cable advices of this date from the principal markets of Great Britain to Geo. A. Cochrane give butter markets as somewhat steadier with a slight advance in prices. Danish is selling at 21@22c, Irish 20@21c. Canadian arriving in increased quantities but its landing condition is so much better than Continental or Irish it is in great favor with buyers and is selling at 19@19½c. There is a little more inquiry for ladles and considerable business could be done at 14@14½c.

Cheese markets are all steady, the very heavy arrivals do not appear to be more than what current consumption can comfortably take care of, the reduced home make assists this. Finest American and Canadian is selling at 9¼@9¾c.

MANCHESTER MARKET, ENGLAND.

Our Copenhagen butter correspondent wires,—Since writing last we have had several showers of rain, and the pastures are now in a better condition. With the higher prices the butter market has calmed down a little, although it is still firm and strong. I don't expect prices to advance any more just now. Exporters are less anxious to pay the high premiums on first rate goods, and supplies seem more equal to demand than of late. The official quotation at Copenhagen has been advanced two kroner, being 13 shillings higher than the corresponding week of last year, but only 5-6 higher than 1897. For next week's North of England markets, 19,137 casks of Danish and Swedish have been shipped, being 1,091 casks less, and 1,543 Finnish or 129 casks less. During the past six weeks, the total supply of Scandinavian butter to Manchester shows a shrinkage of 5,290 casks, hence the higher rates ruling. The recent long spell of dry weather is being largely compensated now, by copious rains. Irish prices have advanced slightly, and remain firm, whilst Canadians and United States have felt the advance. The general impression is that prices have seen the top for some little time to come, and buyers are acting very cautiously and with no desire whatever to speculate. Buying will be purely hand to mouth for weeks to come. Arrivals of margarine via Hull 9,905 packages, via Grimsby 5,093. DOWDALL BROS.

WHY?

Nine out of every ten experienced separator users use "ALPHA" Disc machines only.

Can there be but one reason for it? Is there any room for doubt as to that reason? Most assuredly not.

Could there possibly be any stronger testimonial to the practical superiority of the "ALPHA" disc machines than is afforded by this fact?

If you lack experience in the purchase and use of up-to-date Cream Separators can you not safely follow the practice of nine out of ten of those who have acquired such experience, many of them at large cost to themselves?

A De Laval Catalogue—"Factory" or "Dairy"—will be found to throw a flood of light upon separator differences. It may be had for the asking.

READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

For Sale—Creamery located in good dairy country. Three railroads and express companies. Market convenient. Address "CREAMERY," Lowellville, Ohio. 21-4

Tamworths, ready to wean, $10 each, or $12.50 delivered. Hermanville Farm, P. E. I., Canada. 32-52

Wanted—To correspond with married man that can make brick cheese, that would like a job the year around to take charge of 50 cow dairy and manufacture product into cheese. ALLEN BARBER, Havelack, Neb.

Wanted—A factory size Mason power butterworker. Address B. B. BENNETT, Northville, Mich.

For Sale—4 Reg. Guernsey calves, 2 heifers, 1 bull. Tuberculin tested. C. H. REEVES, Salem, N. J. 23 2

Field Glass $10.00, originally cost $30.00. Nearly new, not a cheap affair; of best French make. Will send it for examination by addressing BOX 392, Cincinnati, Ohio.

Good buttermaker and creameryman wanted to take charge of a 20 cow dairy. $25.00 per month, room and board included. W. A. JOHNSON, Osceola, Ark.

Wanted—A 300 pound second-hand separator and a two-horse tread power, both in good repair. M. D. CUNNINGHAM, Kansasville, Racine Co., Wis.

For Sale—A good creamery in Southern Wisconsin, cheap. A good location for store and creamery combined. M. L. G., care Hoard's Dairyman.

LACTOBUTU is the latest. It is added to bad butter to sweeten it and make it pass for fresh creamery. It is warranted to make nice, elegant butter, no matter how bad it smells or nasty it looks, and is stated to be a decided poison. It requires much faith to eat butter where its source is unknown.

A Great Milk Record.

ED. HOARD'S DAIRYMAN:—The Jersey cow Between, 86664, whose cut we send you, has made for us, all things considered, the best milk record for a year of any cow we have ever owned. In one year her total was 12,133 pounds. She was in calf during this time, six and one-half months. This is an important point to bear in mind. If the cow had been kept empty the probability is that she could have been made to give over 16,000 pounds. We are not aware of any other Jersey cow that has piled up so big a total and that at the same time carried a calf for so great a portion of the year. Her best day was 64¾ pounds, the best seven days, 411½ pounds, the best thirty-one days, 1,753¼ pounds. She made a butter test for us by the churn of 18 pounds, 9¼ ozs. in seven days. The cow was six years and three months old at the beginning of the year's record. No cow on our place was ever fed any milk. In addition to good pasturage in summer and good clover hay in winter, our other feeds are ground oats, corn meal, bran and a little oil meal. In winter we feed, also, ensilage and sugar beets. Between's sire is Billy Russell 26384 and her dam Cocoa Butter 64983. Between is descended from Stoke Pogis 3d on three different lines. It is an interesting fact tonote in this connection that the milk records in the Jersey breed for all periods are held either by descendants of Stoke Pogis 3d or his full brother Stoke Pogis 5th. Jimp, a granddaughter of Stoke Pogis 5th, holds the recodr for a week with 471 lbs., 10 ozs.; Adelaide of St. Lambert, for a day with 82¾ pounds and for a month with 2005¼ pounds. Gertie of Glynllyn holds the record for a year with 16,780 pounds, 3 ounces. These two latter are descendantsof Stoke Pogis 3d. The two cows in the Jersey breed that have the next highest yearly milk records, viz., La Petite Mere 2nd and Matilda 4th, with 16,699½ pounds and 16,153¾ pounds respectively, are daughters of Stoke Pogis 1259 Imp., the sire of Stoke Pogis 3d and Stoke Pogis 5th. Mr. Wheaton's Canadian Dairy Notes.

Cheese Shipments from Canada—Local Markets—English Market—Failing of Summer Milk—Care of Milk.

ED. HOARD'S DAIRYMAN:—Shipments of cheese from Montreal continue to show a large increase over what they were a year ago, though they have been falling off a little of late. From the first of May to July 5th the total shipments from Montreal were 455,950 boxes as compared with 379,704 boxes for the same period last year, an increase of 76,246.

The total shipments from New York up to July 1st were 86,176 as against 93,761 boxes a year ago and from Portland 3,355 boxes as against none last year, making a total from Canada and the United States of 545,481 boxes for 1899 as against 473,465 boxes for the corresponding period of 1898, an increase of 71,916 boxes. Considering the condition of the English market this season this is not a very large increase and should not have any depressing effect upon values.

Last year, at this time, there were large quantities of old stock still unsold on the British market, and in fact some of this old stock was on hand in August. The conditions in this regard this year are quite different. All of 1898 goods were about cleared up at the beginning of this season's make, thus leaving the field clear for the new goods.

This is pretty well shown by the fact that though shipments of cheese have been larger this season, so far there is very little in store in Montreal. Last year at this time large quantities of June cheese were held at Montreal for a higher market which is not the case at the present time, all June goods sold so far, having gone foward to Great Britain.

This feature of the situation gives the market a somewhat healthy outlook. Though prices during the past week or two have dropped a little there are signs to-day (July 8) of a firmer feeling. A few weeks ago it was stated that present prices were being maintained because of short sales of June goods, but as a period of short sales is usually followed by a quick drop in prices, which has not taken place this time, all must conclude that the reason for the market keeping up so well at this season of the year must be found elsewhere.

Prices at the local markets this week have ruled from 8¼ to 8½ for the last half of June make. These, considering everything, are good values and should return the dairyman good profit if he has the right line of cows and cares for their prosperity.

The make this year, especially in the western part of the Province, is not likely to be as large as was expected earlier in the season. Quite a number of the factories report a smaller June make than last year. This is due, perhaps, to the steady increase in the creamery butter business, and also to the dry weather which prevailed in many sections during the latter part of June.

Farther east, conditions have been different, and as large, if not a larger make is the result at most factories. The increase in shipments shows that there must be more cheese being made than last year in same localities.

The shipments of creamery butter from Montreal show a much larger rate of expansion than those of cheese. From the beginning of the season to July 5, the total shipments were 64,870 packages as compared with 40,316 packages for the same period of 1898, an increase of 24,554 packages. But what is surprising is the large falling off in the shipments from New York. For this season so far, the total shipments have only been 11,422 packages, as against 33,056 in 1898, a falling off of 21,634 packages, and thus making the net increase in shipments, from this side, only 2,920 packages.

Prices for Canadian June creamery have been well maintained this season. It is not so very long ago since the best one could expect for our June creamery was 14 cents to 15 cents per pound. Prices during the week (July 8) have ruled at about 17½ to 18 cents for choice creamery, though at the end of the week there was an easier feeling, which brought lower values.

There has been a shortage in the English make this season, owing largely to dry weather, and, perhaps, as we have pointed out before, to the fact that many English dairy farmers are turning their attention more from cheese and butter making to supplying the large cities with milk. The amount of imports into the United Kingdom from France, Norway and Sweden, Russia and Finland have so far not been as large as last year. All this has had considerable effect in keeping up values.

But the shrinkage in the output of these countries, does not account for everything in connection with the improved prices for Canadian creamery. The quality of the goods must get credit for some of it. There are numerous signs to show that Canadian butter is becoming more appreciated every year by Great Britain. It is a good second at any rate to the Danish article, and in many cases sales of Canadian creamery have been made at prices equal to the best Danish.

Everything seems to point to a bright future for the Canadian butter trade, and if the growth of the past few years can be kept up awhile longer our dairymen will be realizing as large a revenue from butter as from cheese. What is required to do this is excellent quality, neat packages, and regular shipments. Our dairymen seem to realize this, and as each season goes by the quality continues to improve, and business is done more on a demand and supply basis.

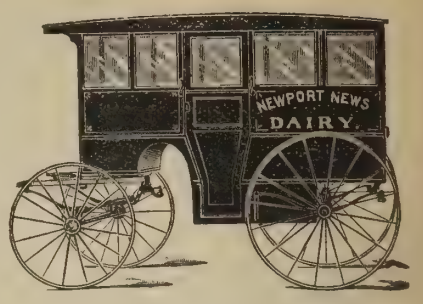
During July and August many patrons of factories are apt to neglect their cows and the milk, owing to the busy haying and harvesting season. But this is a very unwise policy to pursue. The milk needs more care during these two months than at any other time of the year, and to neglect it is only to very much lessen profits by the inferior quality of the product that is sure to result from lack of care and attention.

This neglect is more common with the man who makes dairying a kind of side issue. With him haying and harvesting are the all important things, and the cows and the milk become very insignificant affairs in his estimation. The result is that the cows are not properly cared for; they are milked at irregular hours, and the milk is left largely to take care of itself. If anything goes wrong with it the maker is often blamed, and the patron often wonders why it is sent back to him.

Caring for the cows and her milk is just as important a part of the farm work as any other, even in harvest time, and under no consideration should her milk be neglected at this season of the year. At present prices, the cow and her milk are of more importance than the wheat or the hay crop, and the man who cares for his cows and the milk at all seasons as it should be cared for, is the one who makes dairying a success,

Toronto, Canada. J. W. WHEATON.

Stay By Your Speciality.



(Press Bulletin.)

A creamery patron, who milks cows when butter fat is high and beef low, but who turns his attention to beef when butter fat is low, sends in his dairy report for a year, and at the close remarks: "Profits scarcely visible to the naked eye. What shall we do to be saved?"

Breeding a herd of cows for milk one year, and beef the next is a suicidal policy that no enterprising breeder would dare practice. By this haphazard method, the above patron realized for butter fat $19.63 per cow, per annum. The Kansas Agricultural College scrub herd, pushed along dairy lines, brought an average of $37.75 per cow, per annum. This difference of $18.12 per cow, is what would have been visible to the naked eye, had his cows been handled as the college cows were handled. "What shall we do to be saved?" Settle upon some defini e line of work, study the business in all the details, find out what others are doing in the same lines, make your business a hobby, and above all, stick to it. D. H. OTIS.

Dairy Work in the Maritime Provinces.

Kerosene for Flies.—Operations of the Prince Edward Island Cheese Board.—New Brunswick and Nova Scotia Dairying and Conditions Obtaining.—Governmental and Industrial Encouragement of Dairy Work in Nova Scotia.

ED. HOARD'S DAIRYMAN:—Crops of all kinds are making wonderful progress. Reports from all over the country, state that the loads of milk drawn to the factories these days are truly remarkable. Flies do not bother the cows as much as in some other years. We have tried kerosene to rid the cows of the fly with good suceess. It has the advantage too of being cheap, and ready at hand. We apply it with a small tin spray pump, which forces it on the animal in a fine mist. A gill of kerosene will answer for eight or ten cows two days. With a sprayer like the Little Aspinwall there is practically no waste.

We apply the spray in the evening when taken home for milking. The flies don't bother often and not very much till next evening. The only objection to kerosene is that it evaporates so quickly, and has, therefore, to be applied often. But with this small spraying pump at hand, it is but the matter of a few minutes to spray the backs and legs of the cows. I strongly urge your readers to use the kerosene treatment for getting rid of the flies.

The first meeting of the Prince Edward Island Cheese and Butter Board was held in Charlottetown on Tuesday. Representitives of a good many factories were present. Vice President Jenkins acted as salesman.

The members of the board are to be congratulated on the success of their first meeting, and all present were greatly interested in the proceedings. The several factories, that had cheese boarded, realized the following prices, except Cornwall and Morell, which did not accept the offer of 8⅛ cents; Hazelbrook, 180 boxes, sold at 8⅛ cents, Mr. Dillon buyer; Red House, 119 boxes, sold at 8⅛ cents, Mr. Dillon buyer; Lokeville, 215 boxes, sold at 8⅛ cents, Mr. Dillon buyer; Gowan Bros., 100 boxes, sold at 8⅛ cents, Mr. Dillon, buyer; Kensington, 110 boxes, July cheese, sold at 8⅛ cents, Mr. Dillon buyer; Winsloe, 125 boxes July cheese, sold at 8⅛ cents, Mr. Dillon, buyer; Hillsboro,

140 boxes, sold at 8 5-16, Mr. Harzard buyer; Mt. Steevart 130 boxes, sold at 8 5-16 cents, Mr. Harzard buyer; Cornwall, 214 boxes, part May cheese, not sold; Morell, 200 boxes, July cheese, not sold; Total amount cheese, 1,533 boxes. Lot 16, Dairy Co had 50 boxes butter, for which there was no offer.

The next meeting of the board took place on July 17th at 11 o'clock.

In New Brunswick, sixty cheese factories and twenty creameries are now in full blast. A good deal of the output is being sold to dealers in Halifax for local and domestic trade. Many of the creameries are sending forward their butter to West India market, and but a few are shipping directly to Britain. Job lots of cheeee were quoted in Halifax at the beginning of the week at 9c. Some Ontario butter is being placed on the Halifax market. The large industrial work in coal, mining and fishing in Nova Scotia easily consume much more than the dairies of the Province produce.

This home market for the product is an incentive to dairy work, and affords an advantage not appreciated as it should be. The government of the Province is doing a good deal to encourage agriculture and dairying —much more than either of the other Provinces, and a splendid exhibition, with prizes amounting to $17,000, takes place at the capital, Sept. 23-30th.

A syndicate of Boston and Montreal capitalists has lately formed a company with a capital stock of $20,000,000 to operate the iron and coal fields of Cape Breton. Already the order for the smelting apparatus has been let to parties in Pittsburg to cost $2,5000,000, and the gigantic works will be in operation next year. This will greatly augment the home market for the dairy products of the Maritime Provinces. J. A. M.

Care of Dairy Cows.

[Paper read at the Missouri State Dairy Association by G. B. Lamm, Sedalia, Mo.]

I have divided my subject into two parts, and will treat each part separately:

First Part—Care of dairy cows for their physical comfort.—The amateur in dairying often lavishes money on expensive barns, beautifully painted, and constructed with magnificent proportions; but I have found that comfort can be secured without grand architecture, and even without costly expenditures.

A cow wants a soft, warm bed in winter, clean and fresh, but she cares but little whether her bed be leaves, straw or saw dust. That is left exclusively to the resources of her owner. Her nervous disposition requires protection from extremes in heat and cold, but the covering may be corn fodder, boards or shingles.

Her great distended udder will not allow of abuses, or of long journeys at rapid motion, but of tender treatment when drawing the milk and taking her to and from the pasture.

She is taxed to her utmost in loading the milk with every element necessary for a perfect human food, and excitement disturbs and often retards the process of the perfect elaboration of the milk. During rumination and when secreting the milk the cow demands quiet and comfort.

Easy going management and tender and almost affectionate treatment from youth to age, are most conducive to the development of that domesticated nature of the cow which is so much in harmony with our country home life.

The great draughts of pure water which her wants demand, disturb less the equipoise of the wonder working processes of her stomach when tempered in winter to about 50°.

Her foods are relished best in the absence of the festive fly, but she loves the sunshine and shadow, and is not disturbed by the summer breezes and gentle showers.

In winter she seeks the southern exposure to bask in the sunshine for awhile as though there were healing and restoring properties in its rays for her intricate and heavily taxed nature. In this climate, luxury should always be allowed her, and the dairyman who appreciates the ability and vitality of this noble animal seeks in every way to protect her from inclement weather, muddy barn yards, and the cruelty of every enemy, and give her especially the luxuries, pure air, water and sunshine, which nature affords in abundance.

SECOND PART—Care of dairy cows for profitable results—While the kind hearted dairyman loves to see the marked features of docility, gentleness and beauty perfected in every individual cow, and while his heart rejoices to know that they are cared for tenderly by night and by day, yet he also studies the properties of foods, grains and grasses, so as to supply the cravings of their appetite with such food as may give him the largest possible returns.

He mixes the food for his cows with a master's hand, often deeming it necessary to sell the dairy food he raises on his farm to buy what he needs, in order to give her variety and a well balanced ration. This sometimes insures the largest returns for the least money expended, and he knows, or should know, when a cow has the proper food and a fair chance to do her best.

He harvests his crops at the time when they will do the cow the most good, and then feeds her with a liberal hand.

He avoids the ruinous effects of cows hooking each other by removing the bud of the horn from the calf. This practice has saved the life of many a valuable cow, and more valuable men, and has solved the question of economy of stable building and protection of the weak from the strong. He has his cows come fresh when dairy products will answer best the demands of his market, and saves the waste of over production.

He feeds and milks and salts his cows at regular intervals, because this brings the largest returns, as well as relieves the cow of anxiety. I have seen cows painfully restless because the milker was an hour late. The cow possesses her own devices to get even with negligence and cruelty, and rewards richly every kindness.

The good milker approaches his cow with a kind word and knows how to press the teat against the palm of his hand with the end of his fingers so as not to injure the cow or make her feel uncomfortable when yielding her milk.

While I would have the best possible environment for my cows, yet I would not feed too high, or give too fine or too rich foods, for my experience has been that it weakens vitality and impairs powers to transmit ability to her offspring. She needs from forty to eighty days' rest every year, and will take her rest as a man takes his—on a vacation and among good things to eat. To care for a dairy cow properly, or to tell others how to care for her properly, one must know her habits, her capacity, her surroundings, the climate she is kept in and what special breed she represents. All these may be known to the owner, and when once known, if she is a good cow, he can make of her a valuable acquisition. To know these things is to study a living subject of vast importance to every home, community or state. GEO. B. LAMM.

Sedalia, Mo.

Effect of Exercise on Cows.

The German farmer is compelled to practise all possible economies, and often works his cows in harness. Consequently, the effect of work on milk production is a vital question, and has been studied somewhat. The results of one experiment are reported in the *Milch Zeitung*. Two cows were used in the experiment.

There were eleven periods of two weeks each, alternating work and idleness. The work was a quiet walk in a sweep power, and the power exerted was calculated to correspond during the first period to half a horse power for one hour, the second to half a horse power for two hours, the third to one horse power one hour, and the last too one horse power for two hours. The result may be summarized as follows:

1. The milk yield was reduced to 1.4 pounds per day; the milk was condensed.

2. The percentage of fat was increased, on an average, 10.7 per cent above that in the milk from the cows when not working.

3. The percentage of solids not fat rose somewhat, but not in the same proportion as the fat.

4. The total quantity of fat produced was somewhat increased.

5. The total quantity of solids, not fat produced was reduced, milk sugar the most, and mineral matter the least.

6. Within tne above limits there was no difference in the effect of more or less work.

7. The effect of work showed only a very small reduction in the live weight of the cows.

8. The training of milch cows for moderate, and especially not too long, work may be considered an advantage.

Ths above suggests the query, whether we must not—at least on high priced land—commence the small economies, which enable European farmers to live, and if this gives a hint worth considering to those who have only ten or twenty acres, and to whom the saving of keep of a horse would be quite an item. For every four cows trained for work, the labor of one horse would be saved.

This experiment leads a correspondent of the *Country Gentleman* to query whether some of the alleged differences in milk, with different feeds, are not due to different exercise.

When the cows have been tied up for two huudred days, having no other exercise than chewing their cud, and getting up to eat or drink, are suddenly let out into fresh air, they bellow and kick up their heels like frisky calves, at the smell of the fresh pastures. If the quality of the milk is changed for a few days, who shall say whether it is exercise or feed? That the percentage of fat, when changed, is soon reduced to the normal, is easily explained by the cow's getting accustomed to the new conditions.—*Country Gentleman.*

Reasons for Patronizing the Creamery.

In the Mankato, Minn., *Review*, Mr. Wm. Lewis states the following reasons why, in his estimation, the farmer who has the opportunity should patronize the creamery:

First—You will improve your land by changing from grain to grass.

Second—You will have twelve pay-days every year.

Third—You will not have to ask for credit.

Fourth—You can pay cash for what you buy, save money and make friends.

Fifth—Your bank account will increase from four sources: first, butter fat; second, calves; third, hogs; and fourth, poultry.

Sixth—You will remove hard labor from your wife and daughters, such as carrying milk up and down stairs, in case you have a cellar; no churning or making poor butter.

Seventh—Your pigs would say thank you, if they only knew how.

Eighth—You will not have the blues when it rains for six weeks at a time.

Ninth—Your home surroundings will be pleasant and prosperous, and your neighbors will say: "Behold, what the creamery has done."

Did you ever notice the man in the switching-tower? Does it ever occur to you that the lives of every living person on a train frequently depend on the promptness and intelligence with which he moves the switch levers under his control?

If men could only realize how small a thing may act at the critical instant to switch them from a dangerous track on to one of perfect safety, the yearly deaths from lung diseases would be less by many thousands.

"I had a regular consumptive cough, of which I was afraid, and everybody cautioned and warned me concerning it," says Mr. A. F. Novotny, P. O. Box 1437, New York, in a significant letter to Dr. R. V. Pierce of Buffalo, N. Y. "When I started to take your medicine I was losing *weight rapidly;* I was very pale and had no appetite whatever. I used three bottles of Dr. Pierce's Golden Medical Discovery and now my condition is changed entirely. I do not cough at all; I have gained eight pounds in weight, have gained my healthy color; and my appetite is *enormous.* I can and will recommend your medicine to everybody who may be in need of it; as it is a sure cure, and no humbug as so many other patent medicines are. It is by far the superior of all."

One chapter of Dr. Pierce's great thousand-page illustrated book, The People's Common Sense Medical Adviser tells of nearly one hundred men and women thus promptly switched from the track of death by this matchless remedy. This book is sent free for the bare cost of mailing, 21 one-cent stamps or cloth-bound for 31 stamps. But only one copy to one family.

Eureka Harness Oil is the best preservative of new leather and the best renovator of old leather. It oils, softens, blackens and protects. Use

Eureka Harness Oil

on your best harness, your old harness, and your carriage top, and they will not only look better but wear longer. Sold everywhere in cans—all sizes from half pints to five gallons.
Made by STANDARD OIL CO.

The YOUNG AERATOR And Cooler

Needs no water or ice, removes all odors and gasses. Warranted to keep milk sweet from 6 to 12 hours longer than any machine on the market or money refunded. Circulars free.
W. H. YOUNG, Box 135, Aurora, Ill.

A GOOD SEPARATOR.

Any Separator is better than the old way of making butter. But why not have the very best? They cost no more than the other kind.

The Empire Cream Separators

excel all others for close skimming and ease of running.

We guarantee them to fulfill every claim we make and give perfect satisfaction to every purchaser or your money back. Send for catalogue of the largest line of hand Separators in America.

Sold by Druggists, Saddlery, Agricultural Implement, Flour and Feed and Seed Houses, or The Crescent Chemical Co., Philadelphia, Pa.

A Source of Waste.

The liquid manure is particularly valuable. It contains nearly all the potash, and a large part of the nitrogen that is found in the entire excrement from the animal. The phosphoric acid, some nitrogen and a little potash is in the solid. A ton of fresh urine from cattle is worth about twice as much as a ton of fresh, solid manure. A ton of urine from horses is worth more than three times as much as a ton of the solid excrement. There is no question whatever, about the truth of these figures on the average, and yet the bulk of the urine goes to waste. Some 13 years ago, after trials and experiments and observation, I made up my mind that the best way to save the liquid manure in the stable, where bedding material was plenty, was to have a cement floor and a gutter of the same, if cows were kept, and use absorbents to take up the liquid, and let both solid and liquid go out together. We have a great abundance of wheat straw for absorbent and bedding. A floor was put under our horses. We kept but one cow, so nothing was done to the cow stable. The plan was advocated at the institutes and in the papers. I am safe in saying that hundreds of such floors have been built by our best farmers, as a result. I personally know of some that have been in constant use 12 or 13 years, and are giving entire satisfaction. At first it was thought necessary to make a foundation of stones and fill among them with thin grouting, and stones were used for the sides of gutters. After a little we learned better.

The first floor we built in our horse stable cost three times what there was any need of. We used Portland cement. Several years ago we put in the cow stable floor, and also floors in more horse stalls. They are absolutely perfect. We have visitors from nearly every part of the country, who would report if this were not true. The idea with me was: "Save the manure we must; now, how is the best way." Throw aside prejudice, friends, and believe me, for I have no possible motive only to help you. We have used common cement, as have hundreds of others, with entire success. Portland cement will make a grand floor. It is the best cement made. But common cement is good enough, is cheap, and easily laid by anyone. It is not true that it will not stand, in a stable that is kept from freezing, as all stables should be.

The cement floor and manure shed are undoubtedly all right after one gets them in working order, if one can stand the labor of caring for the manure in this way. As any one can see, there must be a large amount of absorbents used in this case in order to effectually save the liquid, and it seems to us that the same amount, if not considerably less, will accomplish the object more fully and satisfactorily, with a cellar, and at a good deal less expense. The objection raised to the barn cellar will be entirely overcome when a suitable amount of absorbents are used, and the less expense of building and the comparative ease with which the manure can be cared for, make, as we look at it, a strong argument in favor of the cellar, or basement for manure.

When we talk about building cement floors in our barns, and manure sheds separate and apart from them for manure it means an expense that the ordinary farmer will shrink from incurring, however much he may believe in the method. It means also an amount of labor to be performed every day in the year in the way of getting the manure from the stable to the shed—as it must be done with a wheelbarrow or something of the kind—which most any farmer will seek to avoid, unless he is quite sure of a corresponding pecuniary gain.

What is said in regard to the value of the liquid manure and its waste on the majority of our farms is true, and the necessity of adopting some means by which it may be saved should be urged in the strongest terms, but the cheapest and most practical way of accomplishing the same should be adopted by individual farmers.—T. B. TERRY, in *Practical Farmer*.

Producing a Dairy Cow.

Breeding, fitting and training horses for the speed track requires knowledge, judgment, skill and patience. The young animal must be the get of an ancestry whose distinguishing traits are intelligence, action and endurance. He must be bred for speed. Good judgment and skill, gained from experience, must determine whether the young thing gives promise of possessing the qualities essential in an animal bred for speed. Judgment, skill and patience are required in feeding, fitting and training the young thing for a winning performance in the speed contests. This feeding, fitting and training begins at a very early stage of the colt's existence, and is patiently persisted in until the limit of development is reached. The production of a profitable dairy cow begins with the breeding, fitting and training of the calf. The ancestry must be the best we can get for the purpose and the calf must be fed and cared for with that end constantly in view. The food provided must be of the kind and quantity which will most completely develop a milk-giving animal, and not a flesh and fat-producing animal. Nature has furnished this food in the mother's milk and in grass but as we must rob the milk of its fat we must replace this element with something equally good and much cheaper. One cent's worth of corn and flaxseed meal is worth as much to the calf, in combination with sweet skim milk and grass as one pound of butter fat in the whole milk. The value of oats, fed in connection with skim milk and choice hay for a dairy calf food, should not be underestimated. Vigorous growth, exercise and development is what we must get if we are to have a cow capable of large performance. The oats and hay are bulky and increase the capacity of the stomach and digestive organs, and their exercise develops the capacity of the animal for properly taking and using large quantities of bulky milk-making food. Good sweet hay, preferably early cut, well cured clover, should be supplied from the time the calf is three or four weeks old. A clean, well bedded, well ventilated, sunlit stable is the place for calves in winter and the same with screened windows for summer. Milk cows and calves should be kept in screened stables during the heat of the day in summer. There is no profit for the owner or comfort for the cows and calves in fighting flies in the hot sun. Developing the milk-giving habit, which comes with the office of maternity, is an important feature in the fitting and training of a good cow. Maternity should come neither too early or too late. Growth and physical vigor are often sacrificed in forcing the office of maternity upon the young things. Much depends upon the development of the animal, but it may be safely said that no heifer should drop her first calf before she is two years old, and not later than when thirty months of age. The handling of the calves and heifers is also an important feature of this development and training. They should be trained to the cow habit of dependence upon and regard for their master from infancy to maturity. The heifer or cow that does not repay her owner for gentleness, kindness and intelligent care, has not sense or capacity enough for a dairy cow, and the man who withholds these from the good cow has neither sense nor capacity enough for a good dairyman.—*Dairy and Creamery*.

New Process for Preserving Milk.

A process now being introduced in London for the preservation of milk, depends on the use of oxygen and carbonic acid gas. The milk, preferably, of course, as soon as it comes from the cow, is put into self closing bottles, such as are used for aerated waters, and subjected for a fraction of a minute in a special machine to the action of a mixture of the above-named gases at a pressure of several atmospheres. In the first instance the bottles are completely filled, but on being removed from the machine they are left with a small space containing gas, whose pressure serves to retain the stoppers in place. This treatment appears to have the effect of making the milk keep fresh for a considerable time, some samples being quite sweet when examined 50 or 60 days after being bottled.

Moreover, the contents of the bottles, after they have been opened, seem to remain sweet for a longer time than ordinary untreated milk; thus, in one experiment in which portions of the new milk and the preserved milk were placed side by side, the former went sour in three days, while the latter lasted nine. The milk, (according to the "Cable") does not undergo any visible change. It does not effervesce, and no alteration is apparent in its flavor though whether any more subtle changes are produced in its character or composition under the influence of the oxygen is a point that does not seem as yet to have been definitely determined.

Does It Pay to Feed Grain to Dairy Cows In Summer?

A correspondent of the *Practical Farmer* says that by weighing and testing his milk, and keeping exact accounts with 15 cows, and the milk sold from them, he has learned of one mistake he made last year. Until last spring he had always given his cows grain when on grass, but as many writers and farmers claimed that such food was not necessary, he thought to make a saving by omitting the grain feed. Now his accounts, with the same cows for the two years, shows that at the price he is selling milk, 10 cents a gallon, he lost from $6 to $8 per head through the summer, and reckoning the extra value of manure from grain-fed cows, and the extra grain it will take to put the cows back where they were a year ago, his loss will be more than $150 for the season by trying to save grain feeding. The grass was good through the season, and he did not begin feeding until December.

He instances one Holstein cow, fresh in November, 1896, which he bought Feb. 10, 1897. She was then thin in flesh, but he gave her good care, and in June, 1897, with grass and grain feed she gave 1,091½ pounds of milk. She was dry from Jan. 1 to Feb. 21, 1898, but in March, April and May, while he gave grain, she averaged 1,200 pounds a month, and she should have done better in June, 1898, than the June previous if she had received the same grain feed, but she only gave 886½ pounds without the grain, 205 pounds or 24 gallons less than the year before. This would have been worth $2.40, and the grain could have been bought for $1.40 or less for the month.

Butter Bred Bull Calf, 10 MOS. OLD, a Little White.
Very handsome . . . Send For Pedigree. **$50.** J. P. BRADBURY Pomeroy, Ohio.

Hood Farm Jerseys Show Bull Calf for Fairs, 1899. Just the right age, large, grand individual. Solid color and bred right. Dropped Nov. 2, 1898. Sire, Brown Bessie's Son, sire of 7 tested daughters and 2 producing sons. Dam, Virginia's Oonan, 15 lbs. 3 oz. at 2 years old, full sister of Pearl's Oonan 2d, 16 lbs. 10 oz., by Landseer's Pogis, sire of 33 in the list. Write for price. HOOD FARM, Lowell, Mass.

Introduce Milking Jersey Stock INTO YOUR HERD
by buying one of our bull calves. Our herd of 325 has been bred for milk for 17 years. Best blood, size and constitution. Selected stock. **Large English Berkshires,** all ages, at their best. Write for our "little book." **FILSTON FARM, Glencoe, Md.**

St. Lambert Jerseys, all ages, both sexes. Some from **tested cows** at low prices. **W. J. HUSSEY,** Mt. Pleasant, Ohio.

THE Evergreen Farm Herd of A. J. C. C, Jerseys is now headed by St. Lambert of Brodhead, whose pedigree is unequaled in the northwest. We should be pleased to have any one in want of Jerseys to write us for catalogue, stating just what is wanted. N. N. PALMER & SON, Brodhead, Wis.

GREEN PLAIN HERD
POLLED JERSEY CATTLE
Recorded stock FOR SALE. Inquiries promptly answered. **W. H. FORBES, Clifton, Ohio.**

Diplomas Combination 39962.
For Sale—Bulls and Heifers by him out of Fancy's Harry. Signal cows, some of them tested. Write us. **J. E. TYRRELL, Marysville, O.**

ONE YEARLING BULL
Out of a tested dam and **TWO BULL CALVES** out of large milking dams, for sale. Write for price. **W. R. THOMAS, Bellmore, Ind.**

PROSPECT HILL JERSEY HERD.
WISCONSIN PRIZE HERD.
Young Stock from **400 Pound Cows** for sale. Come and see them. **TUBERCULIN TESTED.**
F. H. SCRIBNER, Rosendale, Wis.

ST. OMER HERD Sons of General Signal and double grandsons of Exile of St. L., with 50 to 62½% of his blood, in exchange for good registered cows and heifers due to calve this fall. **JOS. T. HOOPES, Bynum, Md.**

Linden Lawn Farming Co., OLNEY, ILL.
Estab. '90. (*Capital Stock $100,000.00.*) Inc. '97. **640 ACRES.** Breeders of Jersey and Aberdeen Angus Cattle. Poland-China and Yorkshire Hogs, Pure bred Poultry. Send for our plan of Co-operative Farming and Investments. C. S. MACE, Manager.

...FOR SALE...
Pedro Blood!
A GRANDSON OF PEDRO 3187,
carrying 43¾ per cent of his blood. A handsome, thrifty fellow, 10 months old. **Solid grey** in color. Dam made over 400 lbs. butter with second calf. Will send pedigree and photos of sire and dam. **R. C. GREEN, Albion, Wis.**

WILL SELL FOR $100
A GRAND-DAUGHTER OF PEDRO 3187, carrying also, Eurotas blood close through dam, besides plenty other butter blood. Five months old, solid color, extra udder; crated, f. o. b. **W. F. McSPARRAN, Furniss, Pa.**

JERSEY AND HOLSTEIN BULLS
Five good, young bulls of the above breeds for sale at reasonable prices. Also a few good Jersey cows and heifers. Good individuals, superior breeding and heavy milking ancestry. Address
Farm Department, Iowa Agr'l College, AMES, IOWA.

J. D. THOMPSON, Superintendent. FRED P. STORY, Herdsman.
HICKORY HERD,
JOLIET, ILL.,
H. N. HIGINBOTHAM, Prop.,
. . BREEDERS OF . .
Fancy Jersey Cattle.
Service Bull,
PEDRO'S HANDSOME PRINCE, NO. 42794.
The cows in this herd are of the best families of milk and butter producers. We have for sale young bulls by Pedro's Handsome prince and Exile of St. Lambert 55, No. 36073, out of tested cows. Write for prices and pedigrees.

High-Class JERSEYS
The blood of Combination. (Sire of **25** in list) through Brown Bessie, (Champion Butter Cow at World's Fair), and Diploma 16219 sire of 48 in list including Merry Maiden. Young bulls, also cows and heifers bred to Recorder 29239—son of Brown Bessie. Printed pedigrees. State what is wanted. **H. C. TAYLOR, Orfordville, Wis.**

We Have Sold
SEVERAL OF The A. J. C. C. COWS advertised March 17th (see page 92), in fact we quoted prices that made them desirable. There still remain some as well bred as those sold, which we think **genuine bargains.** We also have a few heifers that will be right to breed at time of turning out to grass. For cows, write for List No. 3, giving short pedigrees; for heifers, List No. 2.
WINTERGREEN HILL FARM CO., Scottsville, N. Y.

For Sale . . .
BULL CALF,
Grand-son of the great **Exile of St. Lambert 13657,** sire of 72 tested daughters, "more than any other bull, living or dead." He is thrifty and good size; solid fawn color. His dam has a butter test of 15 lbs. 8½ oz. in seven days. He will be sold cheap.
P. J. COGSWELL, Rochester, N. Y.

Biltmore Farms' JERSEYS.
This is a working herd of 250 of the best native and imported breeding, selected for work at the pail, constitution and individuality. All Tuberculin Tested. Above the fever line, so we can ship anywhere.
SOME CHOICELY BRED
Bull Calves
out of great cows and by the best sires, for sale at Dairymen's Prices. Also large **English Berkshires,** imported and native bred. Apply to
GEO. F. WESTON, Supt., Biltmore, N. C.

MILLER & SIBLEYS JERSEYS.
Ida's Rioter of St. L. leads all other bulls in average for 29 tested daughters, viz.: over 20 lbs. of butter apiece in a week. All full weekly tests, by eight different owners. He weighed 1,760 lbs. His dam's record, 455½ lbs. milk, 30 lbs. 2½ oz. butter (official test) in 7 days. **FOR SALE**—Grandsons and granddaughters of Ida's Rioter of St. L.; also cows in calf to his sons.
224 First Prizes and Sweepstakes at 22 State Fairs or great Expositions. **224** Big cows, Sound cows, Heavy Milkers and Great Butter Makers. Our Adelaide of St. Lambert gave 82¾ lbs. milk in one day, 2005¼ lbs. in one month, the world's Jersey record. Many other championship records. No catalogue. Special literature sent if this paper is mentioned. No animal sold for less than $100. Lowest price for quality. Every animal tuberculin tested before sale, if desired. Also for sale, Children's Ponies and Imported Shropshire Sheep.
Franklin, Venango Co., Pa.

The Lone Tree Jerseys
THE largest collection of **high testing cattle** in the West, including **home-bred** and **Island cows. Show** and **Breeding Stock** always in supply. **Especial attention** given to furnishing **foundation stock for pedigreed herds.** A superb lot of young bulls and heifers now in special offer, including some sure prize winners.
Introduce Fresh Island Blood Into Your Herd.
SIRES IN SERVICE:—The prize winning **IDA'S RIOTER OF ST. LAMBERT 10th,** the champion **CATONO KHEDIVE,** the champion **CZAR COOMASSIE,** and **IMP. GOLDEN BAR,** inbred through his sire, Aristocrat, and his dam, Imp. Sandgate, to Golden Lad, the greatest bull on the Island of Jersey.
Write for what you want. Visitors always welcome. **JOHN E. ROBBINS, Greensburg, Ind.**

Preserving Butter in Brine.

About the most convenient way of preserving a small quantity of butter for future family use is to wrap each lump of butter by itself in a clean and moistened piece of thin muslin, and then pack in stone jars. Tubs will do if perfectly sweet and not leaky. Keep the butter covered with a clear brine made by bringing to boiling point and holding for some minutes a solution of salt in water. It should be made of good butter salt, free from odor, and pure water, and the solution should be saturated, *i. e.*, there should be as much salt added as will dissolve. After boiling slightly for eight or ten minutes, set in a cool place, and when thoroughly cooled, the brine may be poured over the butter.

Be sure to keep the butter well under the brine by means of a slight weight placed on top of it. If the butter is allowed to float, it will come in contact with air and be injured. The boiling removes the air from the brine and destroys the ferments which may be present in the salt or water. Keep the jars covered, and on the bottom of the cellar or other cool place. If tubs are used put them on a board or a stone to prevent the hoops rotting off. It ought to be understood that butter for long keeping must have the buttermilk very thoroughly removed at the time it is made. Treated in the manner indicated, there should be no difficulty in preserving the summer butter surplus for the following winter and spring consumption.—*Farmers' Advocate.*

How An Attack of Epizootic Abortion was Dealt With.

The story I wish to tell is of somewhat ancient date, but the lesson it teaches is as fresh and perhaps as much needed as ever, as this fell plague of abortion is still the bane of many a dairy farmer. If the following simple tale of how it was conquered in my own herd is of any use to my fellow dairymen, its object will have been amply attained. I have no new discovery to herald, simply to tell how remedies, which are at the service of everyone, were successfully applied. The beginning of the mischief dates back to 1890, and its cause or causes are somewhat obscure, but so far as I could make out it began with the purchase of a certain cow, which I now suspect had cast her calf. Up to the time of her purchase, and for some weeks after, everything was going on satisfactorily, but soon after this cow was served we found that the bull was not stopping his cows and gradually it became evident that something was seriously wrong. It was not so much that cows were casting calf as that they were breaking, and coming in season at very irregular intervals, 4, 5, 7, 8 and more weeks. Another bull was obtained, and still the mischief went on, to such an extent that out of fifty-two services during the first six months of 1891, only eight were effective. At this time I was using three bulls. One was kept for the doubtful breeders, one solely for cows that were supposed to be more regular, and one—a young bull—for heifers on and off farm, and these latter were holding quite as badly as the cows.

This went on somewhere about two years until the question of throwing up the business became a pressing one. Cows were being bought in at prices varying from $100 to $125, newly calved and failing to breed; had to be sold off fat at a reduction of $40 to $50, the net average results being that three fat cows brought in two newly calved ones.

During all this time only a small proportion of cows cast a *fœtus* of any size, the usual symptoms—when anything was seen—being perhaps two or three months after service, when a slight brownish colored slime was noticed coming from the vagina, and then a week or two after that the cow would be in season.

Occasionally a small *fœtus* not larger than a rat was seen, five or six weeks after service; a few cows carried their calves six or seven months, but the most frequent sign was the brown slime. About then I saw an article in the "*Journal*" of the R. A. S. E. giving the description of M. Nocard's treatment, and at once decided to try it. The recommendation was to wash the cows every day about the tail, vagina, and hips with a solution of corrosive sublimate and hydrochloric acid, and the hope of a cure in less than two years was held out. This was a rather deferred hope, but was better than nothing, and so the treatment was begun. Every morning this process was gone through, an old washbasin and whiting brush being the means of application. After some weeks of this work and before any improvement was noticeable I fortunately met a well-known veterinarian, and the subject of abortion was broached. He listened to my story with great interest and then said: "That is all very well as far as it goes; but you must inject." Against doing this I quoted the article in question, but he brushed this aside by saying, "You need have no fear of ill consequences, as I have tried it fully," adding, "If you will go with me to the chemist's I will get you the stuff now." As he was a man at the very top of his profession I did not hesitate, but went at once, when I was supplied with half-a-crown's worth of antiseptic discs. These were tried, first on three heifers that had been running for months, which, after two injections were served; two of them holding to the first service, whilst the third did not breed at all. Seeing the very slight pain the injections gave to the heifers, I at once injected every cow on the place that was not in calf, and being by this time firmly convinced that the bull was often the carrier of the infection, also syringed his sheath out with the same solution. The result was that at once and without any further trouble, regular breeding was resumed; of course, some still cast calf and were hard to treat before service, but with hardly an exception every cow treated held to the first service and carried her calf to its full period. One very suggestive experiment was tried. One of the bulls had become absolutely useless and was being fattened off, when it occurred to me to try the effect of thoroughly washing out his sheath. On looking over his record I saw he had served sixteen cows in four months, *and not one was holding.* Two of these cows were selected and thoroughly disinfected by injection, the bull also being treated.

At the first service both of these cows held, carried their calves full time, and bred regularly afterwards. Since then I have had occasional hints of attacks; but whenever I find a cow coming at irregular intervals I always inject her and wash the bull before allowing him to serve. Of course, along with this treatment thorough cleanliness and disinfection of the byres was practiced, but the internal application is the key to the situation. So long as a cow comes at regular intervals of three weeks or a little under I would not hesitate to serve her, changing the bull it may be if she comes frequently; if, however, she exceeds that time by even a week, I believe there has been an abortion and would not serve her without treatment. I have once or twice injected in-calf cows without ill effects, but consider there is no advantage in doing so, and a certain amount of risk, although perhaps not a great one.—*Journal of the British Dairy Farmers' Association.*

Broom Corn Millet.

In the U. S. the term "Broom-corn millet" is at the present time generally applied to this Old-World grass (*Panicum milliaceum.*) It is the "common millet" of Europe, where it has been cultivated for centuries. A "millet," regarded by most authorities as this species, is mentioned by nearly all the early writers on cultivated plants, such, for example, as Theophrastus, Hippocrates, and others, and seems to have been extensively used as a grain in remote times. According to Heer it was much used by Swiss lake dwellers of the stone age, and DeCandolle, on the authority of Regazzoni, says it has also been found in the remains of the lake dwellings of the Varese in Italy.

The nativity of this millet is very uncertain. Although it grows spontaneously throughout southern Europe and many parts of Asia and Africa, there are apparently no really authentic cases of its having been found in a wild state. All the early records speak of it as being cultivated. Some writers, notably Linnæus, regard India as the original home of this millet; but DeCandolle does not consider the records as at all conclusive, and thinks that "its Egypto-Arabian origin is very probable."

Church, in his "Food Grains of India," says: "it was early introduced and is largely cultivated in many parts of India."

It is also extensively grown in China and Japan as well as throughout southern Europe and elsewhere in the Mediterranean regions and north to central Europe. Although introduced into the United States many years ago, it has never been extensively grown over any large extent of territory, and at the present time is much less generally grown than the foxtail millets. It has not met with favor in the South, but in the Northwest is valued highly because of its ability to mature a crop of seed in the short dry season so often prevailing in that region, thus serving to some extent as a substitute for corn.

VARIETIES.

The different cultivated varieties of Broom-corn millet vary more or less in habit of growth and character of the panicle or "head," but the chief distinction lies in the color assumed by the mature seed. Three rather distinct types may be recognized, white, yellow and red. These may intergrade more or less. The red sometimes becomes a very dark brown or almost black, and the "*millet noir ou gris*" (black or gray millet) sold by Vilmorin, of Paris, France, gets its dark gray appearance through the seed being marked with dark stripes on a lighter ground color.

The general color of the growing plant varies considerably in the different varieties. Plants from the yellow seeded varieties are usually light green in color, while those from the red seeded sorts are more often tinged with red, usually in proportion as the seed is light or dark red. Thus, plants of a very dark red seeded Japanese variety grown the past season, maintained a decided reddish-purple tinge throughout the entire period of growth, the color being most pronounced in the young plants, fading out as they became older, and deepening again in the panicle as the plants approached maturity. However, some of the white seeded varieties may often become more or less tinged, as in the case of the variety sold as White French millet. By far the greater number of the varieties offered in the market by seedsmen in this country, and the varieties most widely grown for forage belong to the group with yellowish seed. Such varieties are the Manitoba, California Beauty, French, Turkish and Broom-corn or hog millets. There seems to be little, if any, diffence between these so-called varieties, either in appearance or value.

Of the white seeded sorts the most frequently grown are "White French," "Chinese," or "Chinese White," and "Japanese White." The white seeded varieties seem to be more robust growers, as a usual thing, than either the yellow or the red seeded ones, the most productive being the Japanese White. There are but two of the darker or red seeded varieties that have come into much prominence in this country. They are the "Red French and "Japanese Red."

The large, coarse-growing varieties are valuable for soiling and may be used advantageously in the silo where corn and the heavier-yielding silage crops cannot be successfully grown, or when for any reason these crops are destroyed. The forage does not appear to have the laxative and diuretic action upon the animals eating it produced by the foxtail millets, and there are no harsh, irritating beards. However, objections have been made to it on account of the abundant growth of stiff hairs on the leaves and stems. The yield of forage is, on the average, less than may be obtained from the other millets, but on account of the relatively short season required for its development Broom-corn millet may often produce a crop when the others would not. The yield of seed is large in proportion to the size of the plant, 50 to 60 bushels per acre being frequently reported from the Northwest.—*Year Book, U. S. Department of Agriculture, 1898.*

HOLSTEIN CATTLE! The Choicest Milk and Butter Breed in the World. Write to Wis. Live Stock Ass'n, Appleton, Wis., U.S.A.

SHADY NOOK HERD Holstein-Friesians Choice Chester-White
Pigs 2 to 3 months old, both sexes, for sale.

New York Farm and Dairy Notes.

Sowing Crimson Clover in the Corn.—Humus.

ED. HOARD'S DAIRYMAN:—In times of drouth our attention is called to the value of humus in the soil as a means of retaining moisture. A drouth of three weeks in my locality has afforded an opportunity of noting the difference in soils in carrying crops through a drouth.

The soil on some parts of my farm has been filled with humus by plowing under cover crops or heavy dressings of stable manure. On this soil, where an earth mulch is kept around the plants by frequent cultivation, the plants have continued to grow well during the drouth, while plants in soil deficient in humus ceased to grow.

The matter of sowing crimson clover or other cover crops in the corn is now a timely subject for consideration.

I believe if it can be sown as soon as the last of July, and the soil between corn rows can be finely pulverized with the cultivator, so as to make a good seed bed, it will generally pay the farmer to sow crimson clover between the rows of corn, and take his chances on its living through the winter. In good soil it will make considerable growth before winter, and the fertility the roots will add to the soil will pay for the seeding. Late sowing of crimson clover is very uncertain, and I would not care to sow it in corn after August 1st.

I have before me the results of an experiment made at Cornell University. They show that the value of the cover crops of crimson clover grown there, was much more than the cost, in the capacity the added humus gives to the soil for holding water. One sample of soil taken from where crimson clover had grown, showed 15 per cent of moisture. The sample of soil in which no crimson clover had grown, contained 8.75 per cent of moisture, making a difference of 6.25 per cent in favor of the soil where crimson clover had been grown as a cover crop. The soil in the fields, from which the samples were taken, had been cultivated only to a depth of six inches. The average weight of soil per acre for a depth of six inches is about 750 tons, or 1,500,000 pounds; 6.25 per cent was the increase of moisture in the clover field, and my figuring shows this soil to have a capacity to retain 46⅞ tons of water more per acre than the soil where the crimson clover had not been grown.

It follows from this that the cheapest reservoir in which to store water to carry our crops through a drouth is the humus supplied to the soil by growing and plowing under cover crops of crimson clover, cow peas, rye, etc. The function of humus in the soil is not to make moisture, but to conserve the moisture the soil gets from its natural sources so as to provide a more constant and uniform supply to help carry on the processes of plant growth, for this cannot go on without water to make the plant food in the soil soluble and available, and convey it through the structure of the plant.

For this reason we do not get as good results from commercial fertilizers in soils lacking humus. They do not retain the constant supply of moisture necessary to make the plant food in the fertilizer available.

Now, coming to the question of supplying plant food by plowing under cover crops, we find that our experiment stations have proved that from crimson clover plowed under, nine pounds of nitrogen can be supplied to the soil from the atmosphere for each 10,000 pounds of soil, or 450 pounds per acre. If this amount of nitrogen were purchased in the form of nitrate of soda, it would cost $7.

But this is not all that is gained. The mechanical condition of the soil is so improved that it is cultivated much easier. I have soil that a few years ago was so hard and lumpy that it was worked only with difficulty, and at a great disadvantage. So much vegetable matter has been plowed under that the soil has now become mellow and friable, and it is now a pleasure to work it.

Cow peas are a very desirable crop to sow in the corn, as they furnish a large amount of vegetable matter to plow under. This crop is better adapted to localities where the corn can be planted early, so it will make half its growth early in July. The cow peas should be sown at this time, to make a very large growth. I wish it was a more universal custom to sow something for a cover in the corn, at the last cultivation. If you are so far north that you do not wish to sow crimson clover and cow peas, then sow rye. This will surely live through the winter, and make a cover crop, and when it is plowed under in the spring, it will add humus and some plant food to the soil, although it is not so valuable for this purpose, as crimson clover and cow peas.

In this connection, I think manufacturers of cultivators would make some money, and also encourage the sowing of crimson clover, if they would place on the market an attachment for cultivators for sowing the seed between the rows of corn and other crops. I would think that such a device would find a large sale.

A plan I used to practice was, to use the manure taken from the stables in July, for mulching between the rows of corn. This saved cultivation and retained the moisture. I prefer to draw out the manure, and apply it to the land as fast as it is made, and at this time of year, when there is no other place, unless the meadows are mown, this is sometimes a good practice.

It is now time to begin to feed the early soiling crops, for the pastures need to be supplemented with oats and peas, or other early crops. When feeding these, I think it pays to feed them in the stable, if the work is not much greater, and save all the manure possible. I began July 10th, to feed soiling crops, and feed them in the stable, and all the manure which is made is now daily spread on the land, and we save all there is of it, by having tight gutters, and using absorbents. Through the hot weather of July and August, I like to keep the cows in through the heat of the day, after feeding them, and turn them on the pasture at night. W. J.

Delaware Co., N. Y.

A Talk With our Patrons.

[Paper read before the patrons of the Glendale Creamery Co., Mich., by E. D. Hall.]

It is not my intention, in this paper, to confine myself to any particular part of the dairy subject, but to take a general view of it and speak of some things that would help out most at the present time.

As we enter upon another year's work it would be well to look back over the past year and see if we cannot make some improvements, for it is only as we improve upon our own mistakes and the mistakes of others that we make progress in any given line.

If there had not been improvements in the dairy business during the last twenty-five years the dash churn and the ordinary milk pans would still be in general use. Such, however, is not the case and as there have been improvements in other branches of industry, so also has there been great advancement in the business of dairying.

If success is reached in this day and age of the world it must be attained on a scientific as well as a business like basis. So if you wish to make a success of dairying it must be accomplished along these lines.

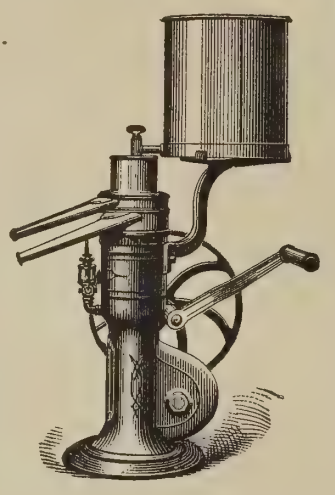
During my connection with the Glendale Creamery we have had patrons who have realized from one cow thirty-five, forty and even forty-five dollars per year.

The first question that presents itself for our consideration then is, whether there is any profit in keeping a cow at such figures, and I think when it is found that one has sold that amount of produce from one cow, and his farm has not been impoverished the least by so doing, you readily arrive at the conclusion that it is profitable and will pay well for the labor expended.

In the next place we should ask ourselves if our cows pay as well as that. If not, why not?

Are our cows what they ought to be?

Are they properly fed? Are our methods of feeding and caring for our cows the most improved? These are important questions to which your attention should be directed, for without the proper kind and quality of feed, and the necessary care and attention, the value of the animal cannot be arrived at, but having properly fed, cared for, and looked after the cow you have only the



The One Successful Color

IT gives entire satisfaction and is the only color that buttermakers should use. It is the one color found in over ninety per cent of the creameries of the country. Butter containing Wells, Richardson & Co.'s Color has the highest standing in the markets. . . .

quantity and quality of the milk to consider.

To do the subject of proper feed and feeding of cows justice, would require more space than I have at this time, but as it is very important, I will discuss it briefly.

And in the first place, I will say that in order to make a cow profitable, she must have good, wholesome food, and plenty of it. The pig that gets only two-thirds of a ration, does not grow up to make a hog, in time to be profitable to its owner.

So it is with a half fed cow. Then again, what the feed shall be, is, to a great extent, left to the sound judgment of each dairyman, for while one man can grow a profitable crop from his farm, of one kind of product, his neighbor might not be able to do so, and would be obliged to raise a different crop to get the same quantity and quality of feed.

As a basis for a good and cheap feed for cows the year round, there is nothing better than ensilage. No one can reach the highest success possible in the dairy business without a silo, by means of which feed can be preserved in its green state.

Most every patron can easily see that he ought to have some means of supplying green feed for his cows during the dry season of the year, which usually lasts from the middle of July until the middle of September.

If one allows his cow to shrink in her milk from the time she is fresh, until time for her to naturally, dry he is committing an injustice to the cow, as well as losing the use of her milk at a time of the year when the prices are the best.

If one has a silo he can keep his cows in good milking condition, and at the same time realize a handsome profit for his trouble. I would recommend, in the absence of a silo, that you arrange to have green feed handy to use during this time of year; for example, a patch of sowed corn near the cow barn would go far in carrying you through the dry season. Besides, it would be cheaper to raise than to furnish the cow a green pasture at this time of year.

In the up-to-date dairies, which I have visited in Michigan and Indiana, the silo was in common use, and the cow had what ensilage she needed the year round.

To properly care for a cow, may be to give her a warm, dry, light and well ventilated stable in winter, or, it may be to give her a well ventilated stable in summer, to keep her from the flies and other insects. In addition to furnishing a cow proper shelter, care and feed, she should be regularly salted, for without this one cannot get the best results. If a butter maker salted one or two churnings a week or whenever he happened to think about it, his patrons would very soon find fault, and they would be justified in doing so. It is equally as essential that a cow be salted regularly.

Considerable has already been said about the care of milk, but I shall mention it briefly, as few patrons seem to realize the importance of having milk in first-class condition. The milk, however, delivered at our factory is much better than I have had occasion to notice at others, but still there is room for improvement.

Butter, like other dairy products, is sold mainly upon the merits of its flavor and unless all milk is perfect, it is impossible to make butter that is what it might be.

Our butter has always sold for the highest market price, which is something that each patron should feel proud of.

Let us, then, as patrons and butter makers, join hand and hand in holding up the standard of our products. E. D. HALL.

Will the Ten Cent Tax Relieve us of the Fraud.

ED. HOARD'S DAIRYMAN:—In the DAIRYMAN of July 7, I read with interest the account of the doings of the New Hampshire dairymen, but question the correctness of their position as expressed in their last resolution, which declared in favor of the proposed ten cent per pound tax on oleomargarine.

Mr. Charles Y. Knight is quoted as making the following statement: "It is a question of fraud that must be fought, not one of quality." While we probably all agree with Mr. Knight, as to the bogus butter business being a fraud, some of us do not agree that the ten cent tax will make it any less a fraud, even if we succeed in securing a law compelling makers to pay a tax of ten cents per pound on butter substitutes or adulterations when colored like butter. If it is wrong to impose on consumers, I take the ground that a ten cent tax does not make it right, but simply acts as a bribe, and if we oppose the fraud, does the bribe make it right?

Should the ten cent tax prove to be prohibitive, then the fraud would be destroyed, but if the object be to prohibit the sale of a fraud, why not ask for a law to prohibit the sale of any such fraud and not have the appearance of being bribe takers, as we have been for years, by licensing the sale of intoxicating liquors. While pretending to be prohibiting the sale of intoxicating liquors by taxing it, we have furnished the strongest protection for the liquor business that could be made and the consumption of alcoholic liquors has grown faster, according to the population during the last quarter of a century than during any similar period since the landing of the pilgrims. And the influence exerted in our government by the liquor interests, is the most corrupting of any known to exist. The power necessary to pass a tax law that is supposed to be prohibitive, could also pass a prohibitory law. And it will be less trouble to enforce a prohibitory law than a tax law.

In the *Harpers Monthly* of July 7, in describing the wonderful plant of Swift & Co., the writer said: "And when you are shown how butterine is made, you cease to wonder at its close resemblance to butter, for it is butter, to which has been added two tasteless, odorless oils, neutral lard and oleo oil." This proves butterine to be adulterated butter, and the color would prevent the chance to impose on unsuspecting consumers, were it not artificially colored to look like butter, simply to enable the maker to sell it at or nearer the price of butter. For one, I prefer to not be an interested partner in the sale of bogus butter, even if taxed; but if possible, would like to see our laws made to prevent food adulteration, unless made and sold for what they are, and at a price that will not rob those who are willing to use the substitutes. If butter substitutes are wanted by the poor, as some claim, let the poor have them at their market value, but usually the price of butter substitutes is regulated according to the amount of butter they contain; yet some will say that certain grades of butterine are as good, or better, than butter. Let us be honest with ourselves, and also with the public, if we expect to improve our conditions. F. L. GASTON.

Normal, Ill.

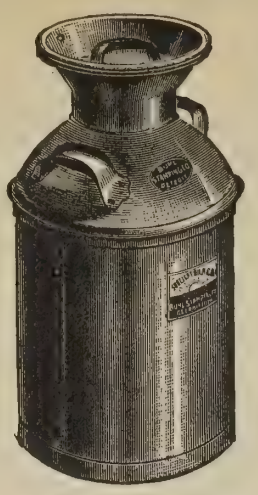
Cream Overrun—Effect of Stabling.

ED. HOARD'S DAIRYMAN:—I am selling separator cream to a creamery by the Babcock test at 15 cents per pound for butter fat. "What per cent of overrun should I expect on 20% cream?"

By stabling our seven cows, in the daytime, our output of cream gained five pounds in four skimmings, without ensilage, and now we are feeding ensilage twice per day and expect to continue increasing, while before we were going lower and lower. A. H.

Burton City, Ohio.

The average overrun will be about eighteen per cent, but may be either higher or lower, according to conditions of churning and working.



Bad Butter.

Made Over by a New Preparation Containing Poison.

Ohio State Dairy and Food Commissioner Blackburn is sending the following warning to the butter dealers of the state:

"It has come to my knowledge that a preparation called "Lactobutu" is on the market to be used to renovate or rework old butter and increase its bulk. Samples of this preparation have been analysed, and it has been found to contain chromate of lead, a poisonous substance which is injurious to health.

"In following the directions a grocer will render himself liable to prosecution by this department for the violation of the oleomargarine law, as the result, if directions are followed, will not be butter under the law, but will be deficient in butter fats and must be considered and sold as oleomargarine."

Buhl Sunlight Milk Cans.

NOTICE OUR PATENT BREAST and BOTTOM HOOPS.

These cans are properly shaped, well tinned and easy to clean. They will last twice as long as any other low priced cans on the market. If your dealer has not got them, send your order direct to the makers and instant shipment will be made. Capacity 5, 8 and 10 gallons. Write for Handbook No. 32, "A Study in Milk Cans."

ILLUSTRATION.

The McCormick Vertical Corn Harvester has an adjustable binding attachment by which the band can be raised or lowered twelve inches. This is a peculiar and exclusive feature which commends it to users. This machine is a profit-maker for farmers. Wherever corn waves its tassels to the breeze, the McCormick Corn Binder is a success to-day.

Nature's Ration for the Calf.

Nature has furnished us her ideal ration in the milk of the range cow, or the cow that has been kept, whether on the farm or ranch range for generations for the sole purpose of growing calves. Her milk contains nature's opinion of the proper percentage of albuminoids, carbohydrates, fat and ash which the young calf requires. She provides for it in the colostrum, or what the farmers sometimes call beastings, or first milk, a nutriment exceedingly rich in nitrogen, best adapted to stimulate its unused powers and also the physic needed to cleanse the hitherto dormant intestinal tract and set the machinery in motion. She gradually shades off this highly nutritious and aperient, or loosening, food, and as gradually increases the percentage of butter fat until the young thing is started on a vigorous, lusty life.
